## PREFACE

This annual report is the result of coordinated field efforts conducted by Washington Department of Fish and Wildlife (WDFW), the Confederated Tribes and Bands of the Yakama Nation (Yakama Nation), Chelan County Public Utility District (Chelan PUD), and BioAnalysts, Inc. An extensive amount of work was conducted in 2006 through 2010 to collect the data needed to monitor the effects of the Chelan County PUD Hatchery Programs. This work was directed and coordinated by the Habitat Conservation Plan (HCP) Hatchery Committee, consisting of the following members: Bill Gale, U.S. Fish and Wildlife Service (USFWS); Rob Jones, National Marine Fisheries Service (NMFS); Joe Miller, Chelan County PUD; Tom Scribner, the Yakama Nation; Mike Tonseth, WDFW; and Kirk Truscott, Confederated Tribes of the Colville Reservation (Colville Tribes).

The approach to monitoring the hatchery programs was guided by the "Conceptual Approach to Monitoring and Evaluating the Chelan County Public Utility District Programs" written by Andrew Murdoch and Chuck Peven. Technical aspects of the monitoring and evaluation program were developed by the Hatchery Evaluation Technical Team (HETT), which consists of the following scientists: Carmen Andonaegui, Anchor Environmental; Matt Cooper, USFWS; Steve Hays, Chelan PUD; Tracy Hillman, BioAnalysts; Tom Kahler, Douglas PUD; Russell Langshaw, Grant PUD; Greg Mackey, Douglas PUD; Joe Miller, Chelan PUD; Andrew Murdoch, WDFW; Keely Murdoch, Yakama Nation; Todd Pearsons, Grant PUD; and Ali Wick, Anchor Environmental. The HETT developed an "Analytical Framework for Monitoring and Evaluating PUD Hatchery Programs" (Hays et al. 2006), which directs the analyses of hypotheses developed under the conceptual approach. Most of the analyses outlined in the Analytical Framework paper will be conducted in 2011 after the fifth year of monitoring.

Most of the work reported in this paper was funded by Chelan PUD. Bonneville Power Administration purchased the Passive Integrated Transponder (PIT) tags that were used to mark juvenile Chinook and steelhead captured in tributaries. This is the fifth annual report written under the direction of the HCP.
"I often say that when you can measure something and express it in numbers, you know something about it. When you cannot measure it, when you cannot express it in numbers, your knowledge is of a meager and unsatisfactory kind. It may be the beginning of knowledge, but you have scarcely in your thoughts advanced to the stage of science, whatever it may be."

Lord Kelvin

## SECTION 1: INTRODUCTION

Chelan PUD implements hatchery programs as part of two Habitat Conservation Plan (HCP) agreements related to the operation of Rocky Reach and Rock Island dams. The HCPs define the goal of achieving no net impact to spring Chinook, summer/fall Chinook, sockeye salmon, steelhead, and coho salmon affected by the operation of these dams. The two HCPs identify general program objectives as "contributing to the rebuilding and recovery of naturally reproducing populations in their native habitats, while maintaining genetic and ecologic integrity, and supporting harvest." The fish resource management agencies initially developed the following general goal statements for each hatchery program, which were adopted by the Hatchery Committee:
(1) Support the recovery of ESA listed species by increasing the abundance of natural adult population, while ensuring appropriate spatial distribution, genetic stock integrity, and adult spawner productivity.

Includes the Wenatchee spring Chinook, Wenatchee summer steelhead, and Methow spring Chinook programs.
(2) Increase the abundance of the natural adult population of unlisted plan species, while ensuring appropriate spatial distribution, genetic stock integrity, and adult spawner productivity. In addition, provide harvest opportunities in years when spawning escapement is sufficient to support harvest.

Includes the Wenatchee sockeye, Wenatchee summer/fall Chinook, Methow summer/fall Chinook, Okanogan summer/fall Chinook, and Okanogan sockeye programs.
(3) Provide salmon for harvest and increase harvest opportunities, while segregating returning adults from natural tributary spawning populations.

Includes the Turtle Rock summer/fall Chinook program.
Thus, there are two different types of artificial propagation strategies that address the different goals of the program: supplementation and harvest augmentation. The supplementation programs primarily focus on increasing the natural production of fish in tributaries. A fundamental assumption of this strategy is that hatchery fish returning to the spawning grounds are "reproductively similar" to naturally produced fish. The second program type, harvest augmentation, focuses on increasing harvest opportunities. This is accomplished by releasing hatchery fish directly into the Columbia River with the intent that returning adults remain segregated from the naturally spawning populations in tributaries.

Monitoring is needed to determine if the programs are performing properly. The HCP Hatchery Committee adopted a monitoring and evaluation (M\&E) approach that will guide the assessment of the hatchery programs. The approach, developed by Murdoch and Peven (2005), identified the following objectives:
(1) Determine if supplementation programs have increased the number of naturally spawning and naturally produced adults of the target population relative to a nonsupplemented population (i.e., reference stream) and the changes in the natural
replacement rate (NRR) of the supplemented population is similar to that of the non-supplemented population.
(2) Determine if the run timing, spawn timing, and spawning distribution of both the natural and hatchery components of the target population are similar.
(3) Determine if genetic diversity, population structure, and effective population size have changed in natural spawning populations as a result of the hatchery program. Additionally, determine if hatchery programs have caused changes in phenotypic characteristics of natural populations.
(4) Determine if the hatchery adult-to-adult survival (i.e., hatchery replacement rate or HRR) is greater than the natural adult-to-adult survival (i.e., natural replacement rate or NRR) and equal to or greater than the program-specific HRR expected value based on estimated survival rates listed in Appendix $D$ in Murdoch and Peven(2005).
(5) Determine if the stray rate of hatchery fish is below the acceptable levels to maintain genetic variation between stocks.
(6) Determine if hatchery fish were released at the programmed size and number.
(7) Determine if the proportion of hatchery fish on the spawning grounds affects the freshwater productivity (i.e., number of juveniles per redd) of supplemented streams when compared to non-supplemented streams.
(8) Determine if harvest opportunities have been provided using hatchery returning adults where appropriate (e.g., Turtle Rock program).

Two additional objectives that were not explicit in the goals specified above but were included in the M\&E approach because they relate to goals and concerns of all artificial production programs include:
(9) Determine whether bacterial kidney disease (BKD) management actions lower the prevalence of disease in hatchery fish and subsequently in the naturally spawning population. In addition, when feasible, assess the transfer of Renibacterium salmoninarum (Rs) infection at various life stages from hatchery fish to naturally produced fish.
(10) Determine if the release of hatchery fish impact non-target taxa of concern (NTTOC) within acceptable limits.

Attending each objective is one or more testable hypotheses (see Murdoch and Peven 2005). Each hypothesis will be tested statistically following the routines identified in Hays et al. (2006). Most of these analytical routines will be conducted at the end of five-year monitoring blocks, as outlined in the M\&E plan (Murdoch and Peven 2005; Hays et al. 2006).

Throughout each five-year monitoring period, annual reports will be generated that describe the M\&E data collected during a specific year. This is the fifth annual report developed under the direction of the M\&E guidance approach (Murdoch and Peven 2005). The purpose of this report is to describe monitoring activities conducted in 2010. Activities included broodstock collection, collection of life-history information, within hatchery spawning and rearing activities, juvenile monitoring within streams, and redd and carcass surveys. Data from reference areas are not
included in this annual report, because the process of selecting reference areas is still occurring. To the extent currently possible, we have included information collected before 2010.

This report is divided into several sections, each representing a different species or stock (i.e., steelhead, sockeye salmon, spring Chinook, and summer Chinook). For all species we provide broodstock information; hatchery rearing history, release data, and survival estimates; disease information; juvenile migration and productivity estimates; redd counts, distribution, and spawn timing; spawning escapements; and life-history characteristics. For salmon species, we also provide information on carcasses.
Finally, we end each section by addressing compliance issues with ESA/HCP mandates. For each Chelan PUD Hatchery Program, WDFW and the PUD are authorized annual take of ESAlisted spring Chinook and steelhead through Section 10 of the Endangered Species Act (ESA), including:

1. ESA Section 10(a)(1)(A) Permit No. 1395, which authorizes the annual take of adult and juvenile endangered upper Columbia River (UCR) spring Chinook and endangered UCR steelhead associated with implementing artificial propagation programs for the enhancement of UCR steelhead. The authorization includes takes associated with adult broodstock collection, hatchery operations, juvenile fish releases, monitoring and evaluation activities, and management of adult returns related to UCR steelhead artificial propagation programs in the UCR region (NMFS 2003a).
2. ESA Section 10(a)(1)(A) Permit No. 1196, which authorizes the annual take of adult and juvenile endangered UCR spring Chinook and endangered UCR steelhead associated with implementing artificial propagation programs for the enhancement of UCR spring Chinook. The authorization includes takes associated with adult broodstock collection, hatchery operations, juvenile fish releases, and monitoring and evaluation activities supporting UCR spring Chinook artificial propagation programs in the UCR region (NMFS 2004).
3. ESA Section 10(a)(1)(A) Permit No. 1347, which authorizes the annual incidental take of adult and juvenile endangered UCR spring Chinook and endangered UCR steelhead through actions associated with implementing artificial propagation programs for the enhancement of non-listed anadromous fish populations in the UCR. The authorization includes incidental takes associated with adult broodstock collection, hatchery operations, juvenile fish releases, and monitoring and evaluation activities associated with non-listed summer Chinook, fall Chinook, and sockeye salmon artificial propagation programs in the UCR region (NMFS 2003b).

## SECTION 2: SUMMARY OF METHODS

Sampling in 2010 followed the methods and protocols described in Murdoch and Peven (2005). In this section we only briefly review the methods and protocols. More detailed information can be found in Murdoch and Peven (2005).

### 2.1 Broodstock Collection and Sampling

Methods for collecting broodstock during 2010 are described in Appendix A in WDFW (2008). Methods for sampling broodstock are described in Appendices A and B in Murdoch and Peven (2005). Generally, broodstock were collected over the migration period (to the extent allowed in ESA-permit provisions) in proportion to their temporal occurrence at collection sites, with inseason adjustments dictated by 2010 run timing and trapping success relative to achieving weekly and annual collection objectives. Pre-season weekly collection objectives are shown in Table 2.1 and assumptions associated with broodstock trapping are provided in Table 2.2.
Table 2.1. Weekly collection objectives for steelhead, sockeye, and Chinook in 2010.

Table 2.2. Biological and trapping assumptions associated with collecting broodstock for the Chelan PUD Hatchery Programs (from Appendix A in Murdoch and Peven 2005).

| Assumptions | Wenatchee Steelhead | Wenatchee Sockeye | Chiwawa Spring Chinook | Wenatchee Summer Chinook | ME/OK Summer Chinook |
| :---: | :---: | :---: | :---: | :---: | :---: |
| Production level | 400,000 yearling smolts | $\begin{gathered} \hline 200,000 \\ \text { subyearlings } \end{gathered}$ | $\begin{aligned} & \text { 672,000 yearling } \\ & \text { smolts } \end{aligned}$ | 864,000 yearling smolts | $\begin{aligned} & \text { 976,000 yearling } \\ & \text { smolts } \end{aligned}$ |
| Broodstock required | 208 adults (not to exceed $33 \%$ of population) | 260 adults (not to exceed $33 \%$ of population) | 379 adults (not to exceed $33 \%$ of population) | 492 adults (not to exceed $33 \%$ of the population) | 556 adults (not to exceed $33 \%$ of the population) |
| Trapping period | 7 July - 12 Nov | 7 July - 28 Aug | 1 May - 12 Sep | $7 \mathrm{Jul}-12 \mathrm{Sep}$ | $7 \mathrm{Jul}-15 \mathrm{Sep}$ |
| \# days/week | 5 | 3 | 4 | 5 | 3 |
| \# hours/day | 24 | 16 | 24 | 24 | 16 |
| Broodstock composition | 50\% wild; 50\% WxW and/or HxW | 100\% wild | Sliding scale; minimum 33\% wild (depends on the number of wild fish) | 100\% wild | 100\% wild |
| Trapping site | Dryden Dam (Tumwater will be used if weekly quota not achieved at Dryden Dam) | Tumwater Dam | Tumwater Dam (hatchery fish only) and the Chiwawa Weir (both hatchery and wild fish) | Dryden Dam (Tumwater will be used if weekly quota not achieved at Dryden Dam) | Wells Dam east ladder |

Several biological parameters were measured during broodstock collection at adult collection sites. Those parameters included the date and start and stop time of trapping; number of each species collected for broodstock; origin, size, and sex of trapped fish; age from scale analysis; and pre-spawn mortality. For each species, trap efficiency, extraction rate, and trap operation effectiveness were estimated following procedures in Appendix B in Murdoch and Peven (2006). In addition, a representative sample of most species trapped but not taken for broodstock were sampled for origin, sex, age, and size (stock assessment). All steelhead trapped were sampled.

### 2.2 Within Hatchery Monitoring

Methods for monitoring hatchery activities are described in Appendix C in Murdoch and Peven (2005). Biological information collected from all spawned adult fish included age at maturity, length at maturity, spawn timing, and fecundity of females. In addition, all fish were checked for tags and females were sampled for disease.

Throughout the rearing period in the hatchery, fish were sampled for growth, health, and survival. Each month, lengths and weights were collected from a sample of fish and rearing density indices were calculated. In addition, fish were examined monthly for health problems following standard fish health monitoring practices for hatcheries. Various life-stage survivals were estimated for each hatchery stock. These estimates were then compared to the "standard" survival rates identified in Table 2.3 to provide insight as to how well the hatchery operations
were performing. Failure to achieve a survival standard could indicate a problem with some part of the hatchery program. However, failure to meet a standard may not be indicative of the overall success of the program to meet the goals identified in Section 1.

Table 2.3. Standard life-stage survival rates for fish reared within the Chelan PUD hatchery programs (from Appendix C in Murdoch and Peven 2005).

| Life stage | Standard survival rate (\%) |
| :---: | :---: |
| Collection-to-spawning (females) | 90 |
| Collection-to-spawning (males) | 85 |
| Unfertilized egg-to-eyed | 92 |
| Unfertilized egg-to-ponding | 98 |
| 30 d after ponding | 97 |
| 100 d after ponding | 93 |
| Ponding-to-release | 90 |
| Transport-to-release | 95 |
| Unfertilized egg-to-release | 81 |

Nearly all hatchery fish from each stock were marked (adipose fin clip) or tagged (coded-wire tag or elastomer tag). Different combinations of marks and tags were used depending on the stock. In addition, Chelan PUD personnel PIT tagged about 10,100 juvenile hatchery spring Chinook in June and about 10,100 steelhead from each release site and production cross (HxW production and WxW production) during September through October. They also tagged about 15,100 juvenile sockeye in late June and early July. Several summer Chinook groups were PIT tagged in 2010. Personnel tagged about 10,100 summer Chinook at Ringold Hatchery in August (half of these were for Turtle Rock and the other half for Chelan Net Pens). In addition, about 10,100 summer Chinook from each of three treatment groups (circular pond R1, circular pond R2, and a standard raceway) were tagged in September. Finally, about 5,100 Okanogan summer Chinook and 5,100 Methow summer Chinook were PIT tagged for each respective program. PIT tags will be used to estimate migration timing and survival rates (e.g., smolt-to-adult) outside the hatchery.
Lastly, the size and number of fish released were assessed and compared to programmed production levels. The goal of the program is that numbers released and their sizes should fall within $10 \%$ of the programmed targets identified in Table 2.4. However, because of constraints due to run size and proportions of wild and hatchery adults, production levels may not be met every year.
Table 2.4. Targets for fish released from the Chelan PUD hatchery programs; CV $=$ coefficient of variation (from Appendix C in Murdoch and Peven 2005).

| Hatchery stock | Size targets |  |  |  |
| :--- | :---: | :---: | :---: | :---: |
| Welease targets |  |  |  |  |  |
|  |  | Fork length $(\mathbf{C V})$ | Weight (g) | Fish/pound |
| Wenatchee Summer Chinook | 864,000 | $176(9.0)$ | 45.4 | 10 |
| Okanogan Summer Chinook | 576,000 | $176(9.0)$ | 45.4 | 10 |
| Methow Summer Chinook | 400,000 | $176(9.0)$ | 45.4 | 10 |
| Turtle Rock Summer Chinook (yearlings) | 200,000 | $176(9.0)$ | 45.4 | 10 |

| Hatchery stock |  | Size targets |  |  |
| :--- | :---: | :---: | :---: | :---: |
|  |  | $112(9.0)$ | 11.4 |
| Chiwawa Spring Chinook | 672,000 |  | 37.8 | 40 |
| Wenatchee Sockeye | 200,000 |  | $133(9.0)$ | 22.7 | 12 |
| Wenatchee Steelhead | 400,000 | $198(9.0)$ | 75.6 | 20 |

### 2.3 Juvenile Sampling

Juvenile sampling within streams included operation of rotary smolt traps, snorkel observations, and PIT tagging. Methods for sampling juvenile fish are described in Appendix E in Murdoch and Peven (2005).

Smolt traps were located on the Wenatchee River at river km 9.6 at the West Monitor Bridge (Lower Wenatchee Trap) and about 0.5 km downstream from the mouth of Lake Wenatchee (Upper Wenatchee Trap), and in the Chiwawa River about 1 km upstream from the mouth (Chiwawa Trap). All traps operated throughout the smolt migration period. The Chiwawa Trap operated throughout most of the year (March through November), but not during icing or extreme high flow conditions. The following data were collected at each trap site: water temperature, discharge, number and identification of all species captured, degree of smoltification for anadromous fish, presence of marks and tags, size (fork lengths and weights), and scales from steelhead and sockeye salmon smolts. Trap efficiencies at each trap site were estimated by using mark-recapture trials conducted over a wide range of discharges. Linear regression models relating discharge and trap efficiencies were developed to estimate daily trap efficiencies during periods when no mark-recapture trials were conducted. The total number of fish migrating past the trap each day was estimated as the quotient of the daily number of fish captured and the estimated daily trap efficiency. Summing the daily totals resulted in the total emigration estimate.

Snorkel observations were used to estimate the number of juvenile spring Chinook salmon, juvenile rainbow/steelhead, and bull trout within the Chiwawa River Basin. The focus of the study was on juvenile spring Chinook salmon. Sampling followed a stratified random design with proportional allocation of sites among strata. Strata were identified based on unique combinations of geology, land type, valley bottom type, stream state condition, and habitat types. A total of 189 randomly selected sites were surveyed during August (Table 2.5). Counts of fish within each sampling site were adjusted based on detection efficiencies, which were related to water temperature. That is, non-linear models that described relationships between water temperatures and detection efficiencies (Hillman et al. 1992) were used to estimate total numbers of fish within sampling sites. These numbers were then converted to densities by dividing total fish numbers by the wetted surface area and water volume of sample sites. Total numbers within a stratum were estimated as the product of fish densities times the total wetted surface or water volume for the stratum. The sum of fish numbers across strata resulted in the total number of fish within the basin. The calculation of total numbers, densities, and degrees of certainty are fully explained in Hillman and Miller (2004).

Working in collaboration with the Integrated Status and Effectiveness Monitoring Program (ISEMP) funded by NOAA Fisheries and Bonneville Power Administration (BPA), crews PIT
tagged juvenile wild Chinook, wild and hatchery steelhead, and wild sockeye salmon throughout the Wenatchee basin. Tags were injected into juvenile fish collected at the Chiwawa Trap, Upper Wenatchee Trap, and the Lower Wenatchee Trap. In addition, fish were collected and tagged in the Chiwawa River upstream from the trap, in Nason Creek, and in the Wenatchee River. The proposed number of wild spring Chinook and steelhead to be tagged at each location is provided in Table 2.6. The goal of this work was to better understand the life-history characteristics of fish in the Wenatchee Basin and to estimate SARs. This in turn improves the ability to detect potential effects of the hatchery program on wild fish.
Table 2.5. Location of strata and numbers of randomly sampled sites within each strata that were sampled in the Chiwawa River Basin in 2010.

| Reach/stratum | River kilometers (RKm) | Number of randomly selected sites |
| :---: | :---: | :---: |
| Chiwawa River |  |  |
| 1 | 0.0-6.1 | 11 |

| Wenatchee River | $500-2,000$ | $500-2,000$ |  |
| Nason Creek | $500-2,000$ | $500-2,000$ |  |
| Lower Wenatchee Trap | $1,000-2,000$ | $500-2,500$ |  |
| Total | $\mathbf{5 , 5 0 0 - 1 7 , 0 0 0}$ | $\mathbf{2 , 5 5 0 - 1 0 , 7 5 0}$ |  |

Survival rates for various juvenile life-stages were calculated based on estimates of seeding levels (total egg deposition), numbers of parr, numbers of emigrants, and numbers of smolts. Total egg deposition was estimated as the product of the number of redds counted in the basin times the mean fecundity of female spawners. Fecundity was estimated from females collected for broodstock using an electronic egg counter. Numbers of emigrants and smolts were estimated at trapping sites and numbers of parr were estimated using snorkel observations only in the Chiwawa Basin. Survival estimates could not be calculated for some stocks (e.g., summer Chinook) because specific life-stage abundance estimates were lacking.

### 2.4 Spawning/Carcass Surveys

Methods for conducting carcass and spawning ground surveys are detailed in Appendix F in Murdoch and Peven (2005). Information collected during spawning surveys included spawn timing, redd distribution, and redd abundance. Data collected during carcass surveys included sex, size (fork length and postorbital-to-hypural length), scales for aging ${ }^{1}$, degree of egg voidance, DNA samples, and identification of marks or tags. The sampling goal for carcasses was $20 \%$ of the spawning population. Crews also conducted snorkel surveys to assess the incidence of precocial fish spawning naturally in streams.
Both redd and carcass surveys were conducted in reaches that encompassed the spawning distribution of most populations. Steelhead surveys were the exception. These surveys were conducted within major spawning areas in the basin and therefore may not capture the entire spawning distribution of the population. Steelhead surveys were conducted during March through June in reaches and index areas described in Table 2.7. Total redd counts were estimated by expanding counts within non-index areas by expansion factors developed within index areas.

[^0]Table 2.7. Description of reaches and index areas surveyed for steelhead redds in the Wenatchee Basin.

Spring Chinook redd and carcass surveys were conducted during August through September in the Chiwawa River (including Rock and Chikamin creeks), Nason Creek, Icicle Creek, Peshastin Creek (including Ingalls Creek), upper Wenatchee River, Little Wenatchee River, and the White River (including the Napeequa River and Panther Creek). Survey reaches for spring Chinook are described in Table 2.8.

Table 2.8. Description of reaches surveyed for spring Chinook redds and carcasses in the Wenatchee Basin.

| Stream | Code | Reach | River mile (RM) |

Surveys for live sockeye and carcass were conducted during August through October in the White, Napeequa, and Little Wenatchee rivers. No sockeye redds were counted in 2010. Live fish counts were used to estimate spawning escapements using the area-under-the-curve (AUC) method.

Table 2.9. Description of reaches surveyed for sockeye salmon carcasses and live fish in the Wenatchee Basin.

| Stream | Code | Reach | River mile (RM) |
| :---: | :---: | :---: | :---: |

|  | Q1 | Mouth to End | $0.0-1.0$ |

Wenatchee summer Chinook redd and carcass surveys were conducted during September through November within ten reaches on the Wenatchee River (Table 2.10). Peak redd counts, map redd counts, and naïve counts were estimated in the Wenatchee River. Map redd counts and naïve counts were only conducted within index areas, not throughout the entire river. Two different methods were used to estimate total redd counts for the entire river. The first method used map counts to expand peak counts. The second relied on naïve counts to expand redd numbers in reaches that did not have map counts. These two approaches are described in Appendix F in Murdoch and Peven (2005).
Table 2.10. Description of reaches and index areas surveyed for summer Chinook redds in the Wenatchee Basin.

|  | O6 | Tonasket Bridge to Zosel Dam | $56.8-77.4$ |
| Similkameen River | S1 | Driscoll Channel to Oroville Bridge | $0.0-1.8$ |
|  | S2 | Oroville Bridge to Enloe Dam | $1.8-5.7$ |

Except for sockeye, total spawning escapements for each population were estimated as the product of total number of redds times the ratio of fish per redd for a specific stock. Fish per redd ratios were estimated as the ratio of males to females sampled at broodstock collection sites and monitoring sites. Total spawning escapement for sockeye salmon was estimated using the AUC approach (where escapement $=$ [AUC/redd residence time] x observer efficiency). This method relied on weekly counts of live sockeye and assumed a redd residence time of 11 days (from Hyatt et al. 2006) and an observer efficiency of $100 \% .^{2}$ In addition, sockeye escapement was estimated using mark-recapture methods. Adult sockeye were PIT tagged at Tumwater Dam and Bonneville Dam ${ }^{3}$ and detected in the Little Wenatchee and White rivers with stationary PIT-tag interrogators.

During carcass surveys for summer Chinook, crews collected tissue samples for genetic analysis. Tissue was collected from the operculum of wild and hatchery carcasses (target of 144 wild and 144 hatchery fish). Sampling within a population was proportional to the distribution of carcasses across survey reaches. That is, samples were collected in all reaches but the number collected within a given reach was proportional to the density of carcasses within that reach. In addition, tissue samples were collected from Wenatchee spring Chinook as part of the spring Chinook reproductive study. Methods for analyzing samples are described in Appendix H in Murdoch and Peven (2005).

Derived metrics calculated from carcass surveys, broodstock sampling, stock assessments, and harvest records included proportion of hatchery spawners, stray rates, age-at-maturity, length-atage, smolt-to-adult survival (SAR), hatchery replacement rates (HRR), exploitation rates,

[^1]harvest rates, and natural replacement rates (NRR). The expected SARs and HRRs for different stocks raised in the Chelan PUD hatchery programs are provided in Table 2.12. Methods for calculating these variables are described in Appendices D, F, and G in Murdoch and Peven (2005) and in "White Papers" developed by the Hatchery Evaluation Technical Team (HETT).

Table 2.12. Expected smolt-to-adult (SAR) and hatchery replacement rates (HRR) for stocks raised in the Chelan PUD Hatchery Programs (from Table 6 in Appendix D in Murdoch and Peven 2005).

| Program | Number of <br> broodstock | Smolts <br> released | SAR | Adult <br> equivalents | Number of <br> smolts/adult | HRR |
| :--- | :---: | :---: | :---: | :---: | :---: | :---: |
| Chiwawa Spring Chinook | 379 | 672,000 | 0.003 | 2,016 | 333 | 5.3 |
| Wenatchee Summer Chinook | 492 | 864,000 | 0.003 | 2,592 | 333 | 5.3 |
| Similkameen Summer Chinook | 328 | 576,000 | 0.003 | 1,728 | 333 | 5.3 |
| Methow Summer Chinook | 228 | 400,000 | 0.003 | 1,200 | 333 | 5.3 |
| Wenatchee Sockeye | 260 | 200,000 | 0.007 | 1,400 | 143 | 5.4 |
| Wenatchee Steelhead | 208 | 400,000 | 0.010 | 4,000 | 100 | 19.2 |

Derived data that rely on CWTs (e.g., HRR, SAR, stray rates, etc.) are five or more years behind release information because of the lag time for returning adult fish to enter the fishery and the processing of tags. Consequently, complete information on rates and ratios based on CWTs is generally only available for years prior to 2004. In addition, some methods for calculating derived variables are still being developed by the HETT. Therefore, estimates of derived data in this report are subject to change after the HETT and Hatchery Committee decide on standard methods for calculating derived data.

## SECTION 3: WENATCHEE STEELHEAD

### 3.1 Broodstock Sampling

This section focuses on results from sampling 2009 and 2010 brood years of Wenatchee steelhead, which were collected at Dryden and Tumwater dams. The 2009 brood begins the tracking of the life cycle of steelhead released in 2010. The 2010 brood is included because juveniles from this brood are still maintained within the hatchery.

## Origin of Broodstock

A total of 208 Wenatchee steelhead from the 2008 return (2009 brood) were collected at Dryden and Tumwater dams (Table 3.1). About $49 \%$ of these were natural-origin (adipose fin present, no CWT, and no elastomer tags) fish and the remaining $51 \%$ were hatchery-origin (elastomer tagged and/or adipose fin absent) adults. Origin was determined by analyzing scales and/or otoliths. The total number of steelhead spawned from the 2009 brood was 159 adults ( $54 \%$ natural-origin and $46 \%$ hatchery-origin).
A total of 211 steelhead were collected from the 2009 return ( 2010 brood) at Dryden and Tumwater dams; 106 ( $50 \%$ ) natural-origin (adipose fin present, no CWT, and no elastomer tags) and 105 ( $50 \%$ ) hatchery-origin (elastomer tagged and/or adipose fin absent) adults. A total of 171 steelhead were spawned; $56 \%$ were natural-origin fish and $44 \%$ were hatchery fish (Table 3.1). Origin was confirmed by sampling scales and/or otoliths.

Table 3.1. Numbers of wild and hatchery steelhead collected for broodstock, numbers that died before spawning, and numbers of steelhead spawned, 1998-2010. Unknown origin fish (i.e., undetermined by scale analysis, no elastomer, CWT, or fin clips, and no additional hatchery marks) were considered naturally produced. Mortality includes fish that died of natural causes typically near the end of spawning and were not needed for the program or were immature fish killed at spawning.

| Brood year | Wild steelhead |  |  |  |  | Hatchery steelhead |  |  |  |  | Total number spawned |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  | Number collected | Prespawn loss | Mortality | Number spawne d | Number released | Number collected | Prespawn loss | Mortality | Number spawned | Number released |  |
| 1998 | 35 | 0 | 0 | 35 | 0 | 43 | 4 | 2 | 37 | 0 | 72 |
| 1999 | 58 | 5 | 1 | 52 | 0 | 67 | 1 | 2 | 64 | 0 | 116 |
| 2000 | 39 | 2 | 1 | 36 | 0 | 101 | 9 | 12 | 60 | 20 | 96 |
| 2001 | 64 | 5 | 8 | 51 | 0 | 114 | 5 | 6 | 103 | 0 | 154 |
| 2002 | 99 | 0 | 1 | 96 | 2 | 113 | 1 | 0 | 64 | 48 | 160 |
| 2003 | 63 | 10 | 4 | 49 | 0 | 92 | 2 | 0 | 90 | 0 | 139 |
| 2004 | 85 | 3 | 0 | 75 | 7 | 132 | 1 | 0 | 61 | 70 | 136 |
| 2005 | 95 | 8 | 0 | 87 | 0 | 114 | 7 | 1 | 104 | 2 | 191 |
| 2006 | 101 | 5 | 0 | 93 | 3 | 98 | 0 | 0 | 69 | 29 | 162 |

| 2009 | 101 | 2 | 0 | 86 | 13 | 107 | 1 | 4 | 73 | 29 | 159 |
| 2010 | 106 | 1 | 1 | 96 | 8 | 105 | 2 | 23 | 75 | 5 | 171 |
| Average | 79 | 3 | 2 | 70 | 4 | 99 | 3 | 7 | 70 | 19 | 140 |

## Age/Length Data

Broodstock ages were determined from examination of scales and/or otoliths. For the 2009 return, both natural-origin and hatchery steelhead consisted primarily of 2 -salt adults (Table 3.2). A small proportion ( $2.4 \%$ ) of the 2009 return, natural-origin steelhead were 3 -salt adults. For the 2010 return, both hatchery and natural-origin steelhead consisted primarily of 1 -salt adults (Table 3.2).

Table 3.2. Percent of hatchery and wild steelhead of different ages (saltwater ages) collected from broodstock, 1998-2010.

| Return year | Origin | Saltwater age |  |  |
| :---: | :---: | :---: | :---: | :---: |
|  |  | 1 | 2 | 3 |
| 1998 | Wild | 39.4 | 60.6 | 0.0 |
|  | Hatchery | 20.9 | 79.1 | 0.0 |
| 1999 | Wild | 50.0 | 48.3 | 1.7 |
|  | Hatchery | 81.8 | 18.2 | 0.0 |
| 2000 | Wild | 56.4 | 43.6 | 0.0 |
|  | Hatchery | 67.9 | 32.1 | 0.0 |
| 2001 | Wild | 51.7 | 48.3 | 0.0 |
|  | Hatchery | 14.9 | 85.1 | 0.0 |
| 2002 | Wild | 55.6 | 44.4 | 0.0 |
|  | Hatchery | 94.6 | 5.4 | 0.0 |
| 2003 | Wild | 13.1 | 85.3 | 1.6 |
|  | Hatchery | 29.4 | 70.6 | 0.0 |
| 2004 | Wild | 94.8 | 5.2 | 0.0 |
|  | Hatchery | 95.2 | 4.8 | 0.0 |
| 2005 | Wild | 22.1 | 77.9 | 0.0 |
|  | Hatchery | 20.5 | 79.5 | 0.0 |
| 2006 | Wild | 28.7 | 71.3 | 0.0 |
|  | Hatchery | 60.3 | 39.7 | 0.0 |
| 2007 | Wild | 40.3 | 59.3 | 0.0 |
|  | Hatchery | 62.1 | 37.9 | 0.0 |
| 2008 | Wild | 65.4 | 33.7 | 0.9 |
|  | Hatchery | 88.8 | 11.2 | 0.0 |
| 2009 | Wild | 39.8 | 57.8 | 2.4 |
|  | Hatchery | 23.4 | 76.6 | 0.0 |
| 2010 | Wild | 65.2 | 33.7 | 1.1 |
|  | Hatchery | 76.5 | 23.5 | 0.0 |
| Average | Wild | 47.9 | 51.5 | 0.6 |
|  | Hatchery | 56.6 | 43.4 | 0.0 |

There was little difference between mean lengths of hatchery and natural-origin steelhead for both the 2009 and 2010 return years (Table 3.3). Natural-origin fish were on average $<1$ to 3 cm larger than hatchery-origin fish of the same age.

Table 3.3. Mean fork length ( cm ) at age (saltwater ages) of hatchery and wild steelhead collected from broodstock, 1998-2010; $\mathrm{N}=$ sample size and $\mathrm{SD}=1$ standard deviation.

| Return year | Origin | Steelhead fork length (cm) |  |  |  |  |  |  |  |  |

## Sex Ratios

Male steelhead in the 2009 return made up about $47 \%$ of the adults collected, resulting in an overall male to female ratio of 0.89:1.00 (Table 3.4). For the 2010 return, males made up about $53 \%$ of the adults collected, resulting in an overall male to female ratio of 1.11:1.00. On average
(1998-2010), the sex ratio is slightly less than the $1: 1$ ratio assumed in the broodstock protocol (Table 3.4).

Table 3.4. Numbers of male and female wild and hatchery steelhead collected for broodstock, 1998-2010. Ratios of males to females are also provided.

| Return year | Number of wild steelhead |  |  | Number of hatchery steelhead |  |  | Total M/F <br> ratio |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |

## Fecundity

Fecundities for Wenatchee steelhead returning in 2009 and 2010 averaged 6,408 and 5,442 eggs per female, respectively, which were similar to the overall average (Table 3.5). Mean fecundities for the 2009 and 2010 returns were at or greater than the 5,400 eggs per female assumed in the broodstock protocol.
Table 3.5. Mean fecundity of wild, hatchery, and all female steelhead collected for broodstock, 19982010.

| Return year | Mean fecundity |  |  |
| :---: | :---: | :---: | :---: |
|  | Wild | Hatchery | Total |
| 1998 | 6,202 | 5,558 | 5,924 |

### 3.2 Hatchery Rearing

## Rearing History

## Number of eggs taken

Based on the unfertilized egg-to-release survival standard of $81 \%$, a total of 493,827 eggs are required to meet the program release goal of 400,000 smolts. Between 1998 and 2010, the egg take goal was reached $54 \%$ of the time (Table 3.6).
Table 3.6. Numbers of eggs taken from steelhead broodstock, 1998-2010.

| Brood year | Number of eggs taken |
| :---: | :---: |
| 1998 | 224,315 |
| 1999 | 303,083 |
| 2000 | 280,872 |
| 2001 | 549,464 |
| 2002 | 503,030 |
| 2003 | 532,708 |
| 2004 | 408,538 |
| 2005 | 672,667 |
| 2006 | 546,382 |
| 2007 | 462,662 |
| 2008 | 439,980 |
| 2009 | 633,229 |
| 2010 | 499,499 |
| Average | 465,879 |

## Number of acclimation days

Juvenile steelhead were transferred from Chelan FH to Turtle Rock FH in December 2009 and from Eastbank FH to Turtle Rock FH in January 2010. At Turtle Rock FH, juvenile steelhead were reared on Columbia River water (range, 114-153 d) before being trucked and released into the Wenatchee River and tributaries. In March 2010, a small group of early HxW steelhead were transferred to Black Bird Pond near Leavenworth for acclimation on Wenatchee River water. Fish were acclimated for 38 d before a volitional release was initiated on 24 April.

Acclimation of Wenatchee juvenile steelhead has occurred on occasion in the Chiwawa Ponds when space is available. At Chiwawa Ponds, steelhead were reared under the same water source as spring Chinook (Chiwawa and Wenatchee River water). Typically, Wenatchee steelhead are reared on Columbia River water from January through April before being trucked and released into the Wenatchee Basin (Table 3.7).

Table 3.7. Water source and mean acclimation period for Wenatchee steelhead, brood years 1998-2009.

| Brood year | Release year | Parental origin | Water source | Number of Days |
| :---: | :---: | :---: | :---: | :---: |

|  |  | Late H x W | Columbia | 84-87 |
|  |  | W x W | Columbia/Nason | 118-120/28 |

## Release Information

## Numbers released

The release of 2009 brood Wenatchee steelhead achieved $121 \%$ of the 400,000 target goal with about 484,772 fish released into the Wenatchee and Chiwawa rivers and Nason Creek (Table 3.8). Distribution of juvenile steelhead released in each of the three basins was determined by the mean proportion of steelhead redds in each basin. About $19.9 \%$ and $22.9 \%$ of the steelhead were released in Nason Creek and the Chiwawa River, respectively. The balance of the program was split between the Wenatchee River downstream from Tumwater Dam (10.4\%) and the Wenatchee River upstream from the dam (36.8\%).
Table 3.8. Numbers of steelhead smolts released from the hatchery, brood years 1998-2009. The release target for steelhead is 400,000 smolts.

| Brood year | Release year | Number of smolts |
| :---: | :---: | :---: |
| 1998 | 1999 | 172,078 |

| 2008 | 2009 | 327,143 |
| 2009 | 2010 | 484,772 |

## Numbers elastomer tagged

Wenatchee hatchery steelhead from the 2009 brood were marked with elastomer tags in the clear tissue posterior of the eye to denote parental origin. About $48 \%$ of the juveniles released were also adipose fin clipped (Table 9).
Table 3.9. Release location and marking scheme for the 1998-2009 brood Wenatchee steelhead.

| 2008 | Wenatchee River | H x W (early) | 10,101 | 59 | 15 | 10,027 |
|  | Wenatchee/Chiwawa rivers | H x W (late) | 10,104 | 106 | 17 | 9,981 |
|  | Chiwawa River/Nason Creek | W x W | 10,101 | 159 | 80 | 9,862 |
| 2009 | Wenatchee/Chiwawa rivers | Hx W (early) | 10,114 | 574 | 11 | 9,529 |
|  | Wenatchee (Blackbird) | H x W (early) | 8,100 | 0 | 0 | 8,100 |
|  | Wenatchee/Chiwawa rivers | H x W (late) | 10,115 | 271 | 11 | 9,833 |
|  | Chiwawa pilot | H x W (early) | 10,107 | 532 | 103 | 9,472 |
|  | Chiwawa River/Nason Creek | W x W | 10,101 | 38 | 3 | 10,060 |

2010 Brood Wenatchee (Turtle Rock) Summer Steelhead (H x H)—A total of 10,100 H x H steelhead were PIT tagged at the Eastbank Hatchery during 11-13 October 2010. These fish were not fed during tagging or for two-three days before or after tagging. These fish averaged 87 mm in length and 7.0 g at time of tagging.

At the end of January 2011, a total of $557 \mathrm{H} \times \mathrm{H}$ steelhead had died (primarily because of Bacterial Cold Water Disease) and 21 others had shed their tags, leaving 9,522 tagged steelhead alive at the end of the month.

2010 Brood Wenatchee (Chelan Falls) Summer Steelhead (W x W)—A total of 10,100 W x W steelhead were PIT tagged at the Chelan Falls Hatchery during 1-3 January 2010. These fish were not fed during tagging or for two-three days before or after tagging. These fish averaged 124 mm in length and 21.0 g at time of tagging.
At the end of January 2011, a total of 202 W x W steelhead had died. None had shed their tags. This left 9,898 tagged steelhead alive at the end of the month.
2010 Brood Wenatchee (Blackbird Pond) Summer Steelhead-A total of 10,101 steelhead were PIT tagged at the Eastbank Hatchery during 4-6 October 2010. These fish were not fed during tagging or for two-three days before or after tagging. These fish averaged 82 mm in length and 6.2 g at time of tagging.

At the end of January 2011, a total of 214 steelhead had died (primarily because of Bacterial Cold Water Disease) and eight others had shed their tags, leaving 9,879 tagged steelhead alive at the end of the month.

2010 Brood Wenatchee (Chiwawa Pond) Summer Steelhead (H x H)—A total of 10,100 H x H steelhead were PIT tagged at the Eastbank Hatchery during 27-30 September 2010. These fish were not fed during tagging or for two-three days before or after tagging. These fish averaged 80 mm in length and 5.8 g at time of tagging.

At the end of January 2011, a total of 42 H x H steelhead had died and 28 others had shed their tags, leaving 10,030 tagged steelhead alive at the end of the month.

## Fish size and condition at release

With the exception of the Blackbird Pond, Chiwawa Ponds, and Rolfhing Pond release, all 2009 brood steelhead were trucked and released as yearling smolts in May of 2010. The other three groups mentioned above were released volitionally beginning 24 April. All three parental groups did not meet the length target and only the early H x W group met or exceeded the weight target. All groups except for the early $\mathrm{H} \times \mathrm{W}$ group met the fish per pound release target. All three groups exceeded the target for coefficient of variation for fork length (Table 3.11).
Table 3.11. Mean lengths (FL, mm), weight ( g and fish/pound), and coefficient of variation (CV) of steelhead smolts released from the hatchery, brood years 1998-2009. Size targets are provided in the last row of the table.

| Brood year | Release year | Parental origin | Fork length (mm) |  | Mean weight |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  |  |  | Mean | CV | Grams (g) | Fish/pound |
| 1998 | 1999 | H x H | 201 | 11.1 | 92.3 | 5 |

## Survival Estimates

Overall survival of Wenatchee steelhead from green (unfertilized) egg to release was slightly below the standard set for the program. This is due in part because of poor green egg-to-eyed egg, eyed egg-to-ponding, and the 30 day after ponding survivals (Table 3.12). The Wenatchee steelhead program, from its inception, has experienced highly variable fertilization rates. It is unknown at this time what mechanisms may be influencing stock performance at these stages.

Table 3.12. Hatchery life-stage survival rates (\%) for steelhead, brood years 1998-2009. Survival standards or targets are provided in the last row of the table.

| Brood year | Collection to spawning |  | Unfertilized egg-eyed | $\begin{gathered} \text { Eyed } \\ \text { egg- } \\ \text { ponding } \end{gathered}$ |  | 100 d after ponding | Ponding to release | Transport to release | Unfertilized egg-release |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  | Female | Male |  |  |  |  |  |  |  |
| 1998 | 92.0 | 100.0 | 85.5 | 91.7 | 99.2 | 98.8 | 97.8 | 99.9 | 76.7 |
| 1999 | 91.2 | 100.0 | 66.9 | 93.0 | 95.9 | 94.9 | 93.1 | 99.7 | 58.0 |

### 3.3 Disease Monitoring

Rearing of the 2009 brood Wenatchee summer steelhead was typical to previous years with fish being held on Chelan spring water, Eastbank well water, and Columbia River water before being released directly into Nason Creek and the Chiwawa and Wenatchee rivers. No significant disease-related mortality events occurred in the 2009 brood steelhead.

### 3.4 Natural Juvenile Productivity

During 2010, juvenile steelhead were sampled at the Upper Wenatchee, Lower Wenatchee, and Chiwawa traps and counted during snorkel surveys within the Chiwawa Basin. Because the snorkel surveys targeted juvenile Chinook salmon, the entire distribution of juvenile steelhead in the Chiwawa Basin was not surveyed. Therefore, the parr numbers presented below represent a minimum estimate.

## Parr Estimates

A total of $25,018( \pm 15.0 \%)$ age-0 $(<100 \mathrm{~mm})$ and $9,616( \pm 13.0 \%)$ age- $1+(100-200 \mathrm{~mm})^{4}$ steelhead/rainbow were estimated in the Chiwawa Basin in August 2010 (Table 3.13 and 3.14). During the survey period 1992-2010, numbers of age-0 and 1+ steelhead/rainbow have ranged from 1,410 to 45,727 and 2,533 to 22,128 , respectively, in the Chiwawa Basin (Table 3.13 and 3.14; Figure 3.1). Numbers of all fish counted in the Chiwawa Basin are reported in Appendix A.

Juvenile steelhead/rainbow were distributed primarily throughout the lower seven reaches of the Chiwawa River (downstream from Rock Creek). Their densities were highest in the lower portions of the river and in tributaries. Age-0 steelhead/rainbow most often used riffle and multiple channel habitats in the Chiwawa River, although they also associated with woody debris in pool and glide habitat. In tributaries they were generally most abundant in small pools. Those that were observed in riffles selected stations in quiet water behind small and large boulders or occupied stations in quiet water along the stream margin. In pool and multiple-channel habitats, age-0 steelhead/rainbow used the same kinds of habitat as age-0 Chinook.
Age-1+ steelhead/rainbow most often used pool, riffle, and multiple-channel habitats. Those that used pools were usually in deeper water than subyearling steelhead/rainbow and Chinook. Like

[^2]age-0 steelhead/rainbow, age-1+ steelhead/rainbow selected stations in quiet water behind boulders in riffles, but the two age groups rarely occurred together. Age-1+ steelhead/rainbow appeared to use deeper and faster water than did subyearling steelhead/rainbow.

Figure 3.1. Numbers of subyearling and yearling steelhead/rainbow trout within the Chiwawa River Basin in August 1992-2010; ND = no data.

## Emigrant and Smolt Estimates

Numbers of steelhead smolts and emigrants were estimated at the Upper Wenatchee, Chiwawa, and Lower Wenatchee traps in 2010.

## Chiwawa Trap

The Chiwawa Trap operated between 5 March and 22 November 2010. During that time period the trap was inoperable for 20 days because of high river flows, debris, snow/ice, mechanical failure, or statewide furlough days. The trap operated in two different positions depending on stream flow; lower position at flows greater than $12 \mathrm{~m}^{3} / \mathrm{s}$ and an upper position at flows less than $12 \mathrm{~m}^{3} / \mathrm{s}$. Monthly captures of all fish collected at the Chiwawa Trap are reported in Appendix B.
A total of 210 wild steelhead/rainbow smolts, 9,921 hatchery smolts, and 1,016 wild parr were captured at the Chiwawa Trap. Nearly all ( $99 \%$ ) of the hatchery smolts were collected in May, while most ( $62 \%$ ) of the wild steelhead smolts were captured during April and May (Figure 3.2). Although steelhead/rainbow parr emigrated throughout the sampling period, most emigrated during April through May and in September (Figure 3.2). No mark-recapture efficiency trials were conducted with steelhead/rainbow at the Chiwawa Trap to estimate total population sizes.

Figure 3.2. Monthly captures of wild smolts, wild parr, and hatchery smolt steelhead/rainbow at the Chiwawa Trap, 2010.

## Upper Wenatchee Trap

The Upper Wenatchee Trap operated nightly between 12 March and 8 July 2010. During the five-month sampling period, a total of 43 wild steelhead/rainbow smolts, 357 hatchery smolts, and 52 wild parr were captured at the Upper Wenatchee Trap. Monthly captures of all fish collected at the Upper Wenatchee Trap are reported in Appendix B.

## Lower Wenatchee Trap

The Lower Wenatchee Trap operated nightly between 4 February and 20 July 2010. During that time period, the trap was inoperable for 19 days because of high river flows, debris, snow/ice, or mechanical failure. During the six-month sampling period, a total of 407 wild steelhead/rainbow smolts, 2,735 hatchery smolts, and 77 wild parr were captured at the Lower Wenatchee Trap. Based on capture efficiencies estimated from the flow model, the total number of wild yearling
steelhead/rainbow that emigrated past the Lower Wenatchee Trap was $36,826( \pm 22,782)$. Most ( $91 \%$ ) of the wild yearling steelhead/rainbow migrated during April and May. Nearly all (96\%) the hatchery yearling steelhead/rainbow migrated during May. Monthly captures of all fish collected at the Lower Wenatchee Trap are reported in Appendix B.

## PIT Tagging Activities

As part of the Integrated Status and Effectiveness Monitoring Program (ISEMP), a total of 3,899 juvenile steelhead/rainbow trout ( 3,735 wild and 164 hatchery) were PIT tagged and released in 2010 throughout the Wenatchee Basin (Table 3.15a). Most of these were tagged in the Chiwawa Basin and Tumwater Canyon. Few were tagged and released at the Upper Wenatchee trap and in the Upper Wenatchee River. A total of 465 juvenile steelhead/rainbow trout were tagged and released at the Lower Wenatchee trap. See Appendix C for a complete list of all fish captured, tagged, lost, and released.

Table 3.15a. Numbers of wild and hatchery steelhead/rainbow trout that were captured, tagged, and released at different locations within the Wenatchee Basin, 2010. Numbers of fish that died or shed tags are also given.

### 3.5 Spawning Surveys

Surveys for steelhead redds were conducted during March through May, 2010, in the Wenatchee River (including Beaver and Chiwaukum creeks), Chiwawa River (including Meadow, Alder, and Clear creeks), Nason Creek (including White Pine, Roaring, and an un-named stream), Icicle Creek, Peshastin Creek (including Mill, Ingalls, Tronsen, Scotty, Shaser, and Schafer creeks), and the White River (including the Napeequa River and Panther Creek). Surveys were conducted in both index and non-index areas throughout the Wenatchee Basin (see Appendix D for more details).

## Redd Counts

A total of 969 steelhead redds were estimated in the Wenatchee Basin in 2010 (Table 3.16). This is about a $146 \%$ increase over the estimate in 2009 (the higher count is partly due to the larger run size in 2010; see Appendix D). Most spawning occurred in the Wenatchee River (39.2\%), Nason Creek (27.9\%), and Icicle Creek (12.4\%) (Table 3.16; Figure 3.3). Peshastin Creek contained $12.2 \%$ of all redds in the Wenatchee Basin. The Little Wenatchee and White Rivers contained $0.4 \%$ and $0.3 \%$, respectively, of the steelhead redds in the Wenatchee Basin. The number of redds estimated in the Chiwawa Basin was just above the average for that area.

Table 3.16. Numbers of steelhead redds estimated within different streams/watersheds within the Wenatchee Basin, 2001-2010; NS = not sampled. Redd counts beginning in 2004 have been conducted within the same areas and with the same methods. Therefore, comparing redd numbers before 2004 with estimates since may not be valid.

Figure 3.3. Percent of the total number of steelhead redds counted in different streams/watersheds within the Wenatchee Basin during March through May, 2010.

## Redd Distribution

Steelhead redds were not evenly distributed among reaches within survey streams in 2010 (Table 3.17). Most of the spawning in the Chiwawa Basin occurred in Reach 1. The number of redds observed in Chikamin Creek and Clear Creek were 11 and 12, respectively. In addition, redds were observed in Alder Creek $(\mathrm{N}=8)$ and Meadow Creek $(\mathrm{N}=3)$. No redds were observed in Rock Creek.

Most of the spawning in the Nason Creek Basin occurred in Nason Creek, primarily in Reach 3. One redd was observed in Whitepine Creek and no spawning was observed in the remaining tributaries. Most spawning activity in the Peshastin Creek Basin was confined to Peshastin Creek proper, while three redds were observed in Tronsen Creek. About $73 \%$ of the spawning in the Wenatchee River occurred upstream from Tumwater Dam (Table 3.17).

Table 3.17. Numbers and percentages of steelhead redds counted within different streams/watersheds within the Wenatchee Basin during March through May, 2010.

| Stream/watershed | Reach | Number of redds | Percent of redds within stream/watershed |

## Spawn Timing

Steelhead began spawning during the first week of March in Peshastin Creek, the second week of March in the Wenatchee River and Icicle Creek, and the third week of March in Nason Creek. Spawning progressed upstream as water temperature increased. Spawning activity appeared to begin once a mean daily stream temperature reached $4.4^{\circ} \mathrm{C}$ and was observed in water temperatures ranging from 3.1 to $9.0^{\circ} \mathrm{C}$. Steelhead spawning peaked in Peshastin Creek the second week of April. Peak spawning occurred the third week in April and the fourth week in April for the Wenatchee River and Nason Creek, respectively (Figure 3.4).

Figure 3.4. Numbers of steelhead redds counted during different weeks in different index areas within the Wenatchee Basin, March through May 2010.

## Spawning Escapement

Spawning escapement for steelhead upstream from Tumwater Dam was calculated as the number of redds (upstream from the dam) times the fish per redd ratio (based on sex ratios estimated at Tumwater Dam using video surveillance). The estimated fish per redd ratio for steelhead in 2010 was 2.33 (Table 3.18). Multiplying this ratio by the total number of redds upstream from the dam
resulted in a total spawning escapement of 1,494 steelhead (Table 3.18). This means that of the 2,270 steelhead counted at Tumwater, about $66 \%$ of them were estimated to have spawned upstream from the dam. This estimate was lower than the average of $48 \%$.

The low estimated spawning escapement in 2010 may have resulted from the difficult survey conditions that biologists experienced in that year. That is, poor survey conditions may have obscured redds and high spring flows prevented post-peak surveys to be conducted in some areas. The effect of other factors, such as pre-spawning mortality, fallback, illegal harvest, etc. remain unknown.

Table 3.18. Numbers of steelhead counted at Tumwater Dam, fish/redd estimates (based on male-tofemale ratios estimated at Tumwater Dam), numbers of steelhead redds counted upstream from Tumwater Dam, total spawning escapement upstream from Tumwater Dam (estimated as the total number of redds times the fish/redd ratio), and the proportion of the Tumwater Dam count that made up the spawning escapement.

| Survey year | Total count at Tumwater Dam | Fish/redd | Number of redds |  |  | Spawning escapement | Proportion of Tumwater count that spawned |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  |  |  | Index area | Non-index area | Total redds |  |  |
| 2001 | 820 | 2.08 | 118 | 19 | 137 | 285 | 0.35 |
| 2002 | 1,720 | 2.68 | 296 | 179 | 475 | 1,273 | 0.74 |
| 2003 | 1,810 | 1.60 | 353 | 88 | 441 | 706 | 0.39 |
| 2004 | 1,869 | 2.21 | 277 | 92 | 369 | 815 | 0.44 |
| 2005 | 2,650 | 1.61 | 828 | 136 | 964 | 1,552 | 0.59 |
| 2006 | 1,053 | 2.05 | 192 | 34 | 226 | 463 | 0.44 |

| 2010 | 2,270 | 2.33 | 517 | 95 | 641 | 1,494 | 0.66 |
| Average ${ }^{\text {a }}$ | 1,658 | 2.11 | 332 | 75 | 394 | 821 | 0.47 |

${ }^{\text {a }}$ The average is based on estimates from 2004 to present.

### 3.6 Life History Monitoring

Life history characteristics of steelhead were assessed by examining fish collected at broodstock collection sites, examining videotape at Tumwater Dam, and by reviewing tagging data and fisheries statistics. Some statistics could not be calculated at this time because few fish have been tagged with CWTs. All steelhead released from the hatchery received elastomer tags and about 40,000 were PIT tagged. With the placement of remote PIT tag detectors in spawning streams in 2007 and 2008, statistics such as origin on spawning grounds, stray rates, and SARs can be estimated more accurately in the future.

## Migration Timing

Sampling at Tumwater Dam indicates that steelhead migrate throughout the year; however, the migration distribution is bimodal, indicating that steelhead migrate past Tumwater Dam in two pulses: one pulse during summer-autumn the year before spawning and another during winter-
spring the year of spawning (Figure 3.5). Most steelhead passed Tumwater Dam during July through October and April. The highest proportion of both wild and hatchery fish migrated during October.

## Steelhead Migration Timing

Figure 3.5. Proportion of wild and hatchery steelhead sampled at Tumwater Dam for the combined brood years of 1999-2010.

Because the migration of steelhead is bimodal, we estimated migration statistics separately for each migration pulse (i.e., summer-autumn migration and winter-spring migration). That is, we compared migration statistics for wild and hatchery steelhead passing Tumwater Dam during the summer-autumn period independent of those for the winter-spring migration period. We estimated the week and month that $10 \%, 50 \%$ (median), and $90 \%$ of the wild and hatchery steelhead passed Tumwater Dam during the two migration periods. We also estimated the mean weekly and monthly migration timing for wild and hatchery steelhead.

Overall, there was little difference in migration timing of wild and hatchery fish enumerated at Tumwater Dam (Table 3.19a and b; Figure 3.5). For both the summer-autumn and winter-spring migration periods, wild and hatchery steelhead arrived at the dam during the same week and month. The mean and median migration timing for wild and hatchery steelhead was also similar. However, at the tail end of both migration periods, on average, wild steelhead appeared to end their migration about one week earlier than hatchery steelhead.

Table 3.19a. The week that $10 \%$, $50 \%$ (median), and $90 \%$ of the wild and hatchery steelhead passed Tumwater Dam during their summer-autumn migration (June through December) and during their winterspring migration (January through May), 1999-2010. The average week is also provided for both migration periods. Migration timing is based on video sampling at Tumwater. The presence of eroded fins and/or missing adipose fins was used to distinguish hatchery fish from wild fish during video monitoring at Tumwater Dam. Estimates also include steelhead collected for broodstock.

| Spawn year | Origin | Steelhead Migration Time (week) |  |  |  |  |  |  |  |  |  |

## Age at Maturity

Nearly all steelhead broodstock collected at Tumwater and Dryden dams lived in saltwater 1 to 2 years (saltwater age) (Table 3.20; Figure 3.6). Very few saltwater age-3 fish returned and those that did were wild fish. On average, there was a difference between the saltwater age at return of
wild and hatchery fish. A greater number of wild fish returned as saltwater age-2 fish than did hatchery fish. In contrast, a greater number of hatchery fish returned as saltwater-1 fish than did wild fish.

Table 3.20. Proportions of wild and hatchery steelhead broodstock of different ages collected at Tumwater and Dryden dams, 1998-2010. Age represents the number of years the fish lived in salt water.

| Sample year | Origin | Saltwater age |  |  | Sample size |
| :---: | :---: | :---: | :---: | :---: | :---: |

## Steelhead Age Structure

Salt Age
Figure 3.6. Proportions of wild and hatchery steelhead of different saltwater ages sampled at Tumwater Dam for the combined years 1998-2010.

## Size at Maturity

On average, hatchery steelhead collected at Tumwater and Dryden dams were about $2-3 \mathrm{~cm}$ smaller than wild steelhead (Table 3.21). This may be related to the fact that more wild steelhead return as saltwater age-2 fish than hatchery steelhead.

Table 3.21. Mean fork length (cm) at age (saltwater ages) of hatchery and wild steelhead collected from broodstock, 1998-2010; N = sample size and SD = 1 standard deviation.

| Return year | Origin | Steelhead fork length (cm) |  |  |  |  |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |

## Contribution to Fisheries

Nearly all harvest on Wenatchee steelhead occurs within the Columbia basin. Harvest rates on steelhead in the Lower Columbia River fisheries (both tribal and non-tribal) are generally less than 5-10\% (NMFS 2004). WDFW regulates steelhead harvest in the Upper Columbia. Under certain conditions, WDFW may allow a harvest on hatchery steelhead (adipose fin clipped fish). The intent is to reduce the number of hatchery steelhead that exceed habitat seeding levels in spawning areas and to increase the proportion of wild steelhead in spawning populations.

## Origin on Spawning Grounds

At this time, origin of steelhead (wild or hatchery) on spawning grounds cannot be determined precisely. However, based on scales collected during steelhead run composition sampling at Dryden Dam in 2008 (2009 spawners), naturally produced steelhead made up about $23 \%$ of the escapement. More precise estimates of wild and hatchery spawners within tributaries can be generated after remote PIT tag detectors are installed within spawning tributaries.

## Straying

Stray rates are currently difficult to estimate because fish are not handled on spawning grounds. As remote PIT-tag detectors are installed in spawning streams, we will be able to more accurately determine steelhead stray rates.

## Genetics

A report on the genetic analysis of Wenatchee steelhead will be completed in the future.

## Proportion of Natural Influence

Another method for assessing the genetic risk of a supplementation program is to determine the influence of the hatchery and natural environments on the adaptation of the composite population. This is estimated by the proportion of natural-origin fish in the hatchery broodstock ( pNOB ) and the proportion of hatchery-origin fish in the natural spawning escapement ( pHOS ). The ratio $\mathrm{pNOB} /(\mathrm{pHOS}+\mathrm{pNOB})$ is the Proportion of Natural Influence (PNI). The larger the ratio ( PNI ), the greater the strength of selection in the natural environment relative to that of the hatchery environment. In order for the natural environment to dominate selection, PNI should be greater than 0.5 (HSRG/WDFW/NWIFC 2004).

For brood years 2001-2010, the PNI was generally equal to or greater than 0.4 (Table 3.22). This indicates that the hatchery environment has an equal or greater influence on adaptation of Wenatchee steelhead than does the natural environment.
Table 3.22. Proportionate natural influence (PNI) of the Wenatchee steelhead supplementation program for brood years 2001-2010. PNI was calculated as the proportion of naturally produced steelhead in the hatchery broodstock ( pNOB ) divided by the proportion of hatchery steelhead on the spawning grounds (pHOS) plus pNOB. NOS = number of natural-origin steelhead on the spawning grounds; HOS = number of hatchery-origin steelhead on the spawning grounds; NOB = number of natural-origin steelhead collected for broodstock; and $\mathrm{HOB}=$ number of hatchery-origin steelhead included in hatchery broodstock.

| Brood year | Spawners $^{\mathbf{a}}$ |  |  | Broodstock |  |  | PNI |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  | NOS | HOS | pHOS | NOB | HOB | pNOB |  |
| 2001 | 158 | 127 | 0.45 | 51 | 103 | 0.33 | 0.43 |
| 2002 | 731 | 542 | 0.43 | 96 | 64 | 0.60 | 0.59 |
| 2003 | 356 | 350 | 0.50 | 49 | 90 | 0.35 | 0.42 |
| 2004 | 371 | 444 | 0.55 | 75 | 61 | 0.55 | 0.50 |
| 2005 | 690 | 862 | 0.56 | 87 | 104 | 0.46 | 0.45 |
| 2006 | 253 | 210 | 0.45 | 93 | 69 | 0.57 | 0.56 |
| 2007 | 145 | 115 | 0.44 | 76 | 58 | 0.57 | 0.56 |
| 2008 | 168 | 279 | 0.62 | 77 | 54 | 0.59 | 0.48 |
| 2009 | 171 | 545 | 0.76 | 86 | 73 | 0.57 | 0.24 |
| 2010 | 524 | 970 | 0.65 | 96 | 75 | 0.56 | 0.46 |
| Average | $\mathbf{3 5 7}$ | $\mathbf{4 4 4}$ | $\boldsymbol{0 . 5 4}$ | 79 | 75 | $\boldsymbol{0 . 5 1}$ | $\boldsymbol{0 . 4 9}$ |

${ }^{\text {a }}$ Proportions of natural-origin and hatchery-origin spawners were determined from video tape at Tumwater Dam. Therefore, these PNI estimates are appropriate for steelhead spawning upstream from Tumwater Dam. They may not represent PNI for steelhead spawning downstream from Tumwater Dam.

## Natural Replacement Rates

Natural replacement rates (NRR) were calculated as the ratio of natural-origin recruits (NOR) to the parent spawning population. For brood years 1989-2001, NRR in the Wenatchee averaged 0.83 (range, 0.07-3.13) (Table 3.23). NRRs for more recent brood years will be calculated as soon as the data are available.

Table 3.23. Spawning escapements, natural-origin recruits (NOR), and natural replacement rates (NRR) for Wenatchee steelhead, 1989-2004. Numbers of hatchery and wild steelhead were based on radio telemetry results, numbers of steelhead passing Priest and Wells dams, and the number of steelhead harvested or removed for broodstock. (The numbers in this table may change as the HETT and HC refine the methods for estimating steelhead escapement, NORs, and NRRs.)

| Brood year | Spawning escapement |  |  | NOR | NRR |
| :---: | :---: | :---: | :---: | :---: | :---: |
|  | Hatchery | Wild | Total |  |  |
| 1989 | 1,849 | 1,001 | 2,851 | 342 | 0.122 |
| 1990 | 1,487 | 936 | 2,423 | 321 | 0.141 |
| 1991 | 990 | 481 | 1,471 | 262 | 0.218 |
| 1992 | 1,333 | 888 | 2,221 | 241 | 0.118 |
| 1993 | 2,951 | 566 | 3,516 | 342 | 0.068 |
| 1994 | 985 | 309 | 1,294 | 427 | 0.265 |
| 1995 | 1,637 | 303 | 1,940 | 1,037 | 0.220 |
| 1996 | 1,036 | 409 | 1,445 | 1,609 | 0.717 |
| 1997 | 245 | 269 | 514 | 1,225 | 3.129 |
| 1998 | 391 | 278 | 668 | 796 | 1.832 |
| 1999 | 114 | 268 | 382 | 1,260 | 2.085 |
| 2000 | 738 | 406 | 1,144 | 1,301 | 1.101 |
| 2001 | 1,065 | 773 | 1,838 | NA | 0.707 |
| 2002 | NA | NA | 530 | NA | NA |
| Average | 1,140 | 1,670 | 731 | 0.825 |  |

## Hatchery Replacement Rates

Hatchery replacement rates were estimated as hatchery adult-to-adult returns. These rates should be greater than the NRRs and greater than or equal to 19.2 (the calculated target value in Murdoch and Peven 2005). In years with data, HRRs and adjusted HRRs were consistently greater than NRRs (Table 3.24). In contrast, HRRs exceeded the estimated target value of 19.2 in only one year and adjusted HRRs exceeded the estimated target in two of the six years (Table 3.24).

Table 3.24. Hatchery replacement rates (HRR), adjusted HRR (for estimated tag loss), and NRR for Wenatchee steelhead, 1998-2006. (The numbers in this table may change as the HETT and HC refine the methods for estimating steelhead HRRs and NRRs.)

| Brood year | HRR | Adjusted HRR | NRR |
| :---: | :---: | :---: | :---: |
| 1998 | 1.89 | 3.49 | 1.83 |
| 1999 | 15.47 | 23.16 | 2.09 |
| 2000 | 2.60 | 3.33 | 1.10 |
| 2001 | 57.97 | 63.37 | 0.71 |
| 2002 | 11.76 | 12.18 | NA |
| 2003 | 6.56 | 6.56 | NA |
| 2004 | NA | NA | NA |

| Brood year | HRR | Adjusted HRR | NRR |
| :---: | :---: | :---: | :---: |
| Average | 16.04 | 18.68 | 1.43 |

## Smolt-to-Adult Survivals

Smolt-to-adult ratios (SARs) are calculated as the number of returning hatchery adults divided by the number of tagged hatchery smolts released. SARs are generally based on CWT returns. However, Wenatchee steelhead have not been extensively tagged with CWTs. Therefore, elastomer-tagged fish were used to estimate SARs from release to capture at Priest Rapids Dam. Two different estimates are provided. One (unadjusted) is based on elastomer tag recaptures at Priest Rapids Dam; the other (adjusted) is corrected for tag loss after release (based on the number of unmarked hatchery adults that could not be accounted for). SARs for steelhead may change once a more accurate methodology for estimating adult survival has been developed.
Unadjusted SARs for Wenatchee steelhead ranged from 0.0017 to 0.0307 (mean $=0.0076$ ) for brood years 1996-2006 (Table 3.25). Accounting for post-release tag loss, SARs ranged from 0.0016 to 0.0336 (mean $=0.0105$ ) for brood years 1998-2005.

Table 3.25. Smolt-to-adult ratios (SARs) for Wenatchee hatchery steelhead, 1996-2006; NA $=$ not available. Unadjusted estimates were based on elastomer tags recaptured at Priest Rapids Dam. Adjusted estimates were corrected for tag loss after release.

| Brood year | Number of tagged smolts <br> released | SAR (unadjusted) | SAR (adjusted) |
| :---: | :---: | :---: | :---: |
| 1996 | 348,693 | 0.0034 | NA |
| 1997 | 429,422 | 0.0041 | NA |
| 1998 | 172,078 | 0.0009 | 0.0016 |
| 1999 | 175,661 | 0.0110 | 0.0165 |
| 2000 | 184,639 | 0.0017 | 0.0022 |
| 2001 | 335,933 | 0.0307 | 0.0336 |
| 2002 | 302,060 | 0.0063 | 0.0065 |
| 2003 | 374,867 | 0.0027 | 0.0027 |
| 2004 | 276,773 | NA | NA |
| 2005 | NA | NA | NA |
| Average | $\mathbf{2 7 8 , 3 5 5}$ | $\mathbf{0 . 0 0 7 6}$ | $\boldsymbol{0 . 0 1 0 5}$ |

### 3.7 ESA/HCP Compliance

## Broodstock Collection

Collection of BY 2009 broodstock for Wenatchee steelhead at Tumwater and Dryden dams began on 1 July and ended on 25 October 2008 and represented a slightly shortened collection duration from the 1 July - 12 November collection period detailed in the 2008 broodstock collection protocol. The broodstock collection protocols specified a total collection of 208 steelhead, including 104 natural-origin steelhead. Actual broodstock collection totaled 208
steelhead collected at Tumwater and Dryden dams, including 102 natural-origin fish (49\% of the total collection). The total number and proportion of natural-origin steelhead in the broodstock were less than the 104 and slightly below the $50 \%$ values identified in the 2008 protocol and ESA Permit 1395, respectively.

About 233 and 1,033 steelhead were handled and released at Dryden Dam and Tumwater Dam, respectively, during BY 2009 Wenatchee steelhead broodstock collection. These fish were released because the weekly quota for hatchery or wild steelhead had been attained, but not both, or because they were non-target (red VIE), or they were unidentifiable hatchery-origin steelhead. All steelhead released were allowed to fully recover from the anesthesia and released immediately upstream from the trap sites.
In addition to steelhead encountered at Dryden Dam during steelhead broodstock collection, 59 spring Chinook salmon were captured and released unharmed immediately upstream from the trap facility. Consistent with ESA Section 10 Permit 1395 impact minimization measures, all ESA species handled at this site were subject of water-to-water transfers.

## Hatchery Rearing and Release

The 2009 brood Wenatchee steelhead reared throughout all life-stages without significant mortality (defined as $>10 \%$ population mortality associated with a single event). However, the 2009 brood had poor fertilization to eyed-egg and eyed-egg to ponding survival resulting in an unfertilized-to-release survival of $76.6 \%$, which was less than the program target of $81 \%$ (see Section 3.2).

Juvenile rearing occurred at three separate facilities including Eastbank Fish Hatchery, Chelan Falls Fish Hatchery, and Turtle Rock Fish Hatchery. Multiple facilities were used to take advantage of variable water temperatures to manipulate growth of juveniles from different parental crosses. Typically, wild steelhead spawn later than their hatchery cohort and are therefore reared at Chelan Falls Fish Hatchery on warmer water to accelerate their growth so they achieve a size at release similar to HxH and HxW parental cross progeny reared on cooler water at Eastbank Fish Hatchery. All parental cross groups received final rearing at Turtle Rock Fish Hatchery on Columbia River surface water before direct release (scatter planting) in the Wenatchee River basin.

The 2009 brood steelhead smolt release in the Wenatchee Basin totaled 484,772 smolts, representing about $121 \%$ of the program target of 400,000 smolts identified in the Rocky Reach and Rock Island Dam HCPs and in ESA Section 10 Permit 1395. As specified in ESA Section 10 Permit 1395, all steelhead smolts released were externally marked or tagged and a representative number were PIT tagged (see Section 3.2)

## Hatchery Effluent Monitoring

Per ESA Permits 1196, 1347, and 1395, permit holders shall monitor and report hatchery effluents in compliance with applicable National Pollution Discharge Elimination Systems (NPDES) (EPA 1999) permit limitations. There were no NPDES violations reported at Chelan PUD Hatchery facilities during the period 1 January 2010 through 31 December 2010. NPDES monitoring and reporting for Chelan PUD Hatchery Programs during 2010 are provided in Appendix E.

## Smolt and Emigrant Trapping

Per ESA Section 10 Permit No. 1395, the permit holders are authorized a direct take of $20 \%$ of the emigrating steelhead population and a lethal take not to exceed $2 \%$ of the fish captured (NMFS 2003). Based on the estimated wild steelhead population (smolt trap expansion) and hatchery juvenile steelhead population estimate (hatchery release data) for the Wenatchee Basin, the reported steelhead encounters during the 2010 emigration complied with take provisions in the Section 10 permit and are detailed in Table 3.26. Additionally, juvenile fish captured at the trap locations were handled consistent with provisions in ESA Section 10 Permit 1395 Section B.
Table 3.26. Estimated take of Upper Columbia River steelhead resulting from juvenile emigration monitoring in the Wenatchee Basin, 2010. NA = not available.

${ }^{\mathrm{b}} 2010$ smolt release data for the Wenatchee basin.
${ }^{c}$ Estimated parr emigrating past juvenile trap sites (Miller et al. 2009)
${ }^{\mathrm{d}}$ Mortality includes trapping and PIT tag mortalities.

## Spawning Surveys

Steelhead spawning ground surveys were conducted in the Wenatchee Basin during 2010, as authorized by ESA Section 10 Permit No. 1395. Because of the difficulty of quantifying the level of take associated with spawning ground surveys, the Permit does not specify a take level associated with these activities, even though it does authorize implementation of spawning ground surveys. Therefore, no take levels are reported. However, to minimize potential impacts
to established redds, wading was restricted to the extent practical, and extreme caution was used to avoid established redds when wading was required.

## Stock Assessment at Priest Rapids Dam

Upper Columbia River steelhead stock assessment sampling at Priest Rapids Dam (PRD) is authorized through ESA Section 10 Permit No. 1395 (NMFS 2003). Permit authorizations include interception and biological sampling of up to $10 \%$ of the UCR steelhead passing PRD to determine upriver adult population size, estimate hatchery to wild ratios, determine age-class contribution, and evaluate the need for managing hatchery steelhead consistent with ESA recovery objectives, which include fully seeding spawning habitat with naturally produced Upper Columbia River steelhead supplemented with artificially propagated enhancement steelhead (NMFS 2003). The 2009-10 run-cycle report (BY 2009) for stock assessment sampling at Priest Rapids Dam was compiled under provisions of ESA Section 10 Permit 1395. Data and reporting information are included in Appendix F.

## SECTION 4: WENATCHEE SOCKEYE SALMON

### 4.1 Broodstock Sampling

This section focuses on results from sampling 2008 and 2009 Wenatchee sockeye broodstock, which were collected at Tumwater Dam. The 2008 brood begins the tracking of the life cycle of sockeye that were released as parr into Lake Wenatchee in 2009 and some of which began smolt migrations in 2010. The 2009 brood is included because juveniles from this brood were released as parr in the lake in 2010. Complete information is not currently available for the 2010 brood (this information will be provided in the 2011 annual report). Collection of sockeye broodstock targets naturally produced fish and equal numbers of male and female fish.

## Origin of Broodstock

The 2008 broodstock consisted of naturally produced sockeye collected at Tumwater Dam between 21 July and 6 August 2008 (Table 4.1). A total of 245 naturally produced sockeye were spawned. The 2009 broodstock consisted of naturally produced Wenatchee sockeye salmon collected at Tumwater Dam between 11 July and 21 August 2009 (Table 4.1). A total of 214 naturally produced sockeye were spawned.

Table 4.1. Numbers of wild and hatchery sockeye salmon collected for broodstock, numbers that died before spawning, and numbers of sockeye spawned, 1989-2009. Unknown origin fish (i.e., undetermined by scale analysis, no CWT or fin clips, and no additional hatchery marks) were considered naturally produced. Mortality includes sockeye that died of natural causes typically near the end of spawning and were not needed for the program, surplus sockeye killed at spawning, sockeye that died but were not recovered from the net pens, and sockeye that may have jumped out of the net pens.

| Brood year | Wild sockeye |  |  |  |  | Hatchery sockeye |  |  |  |  | Total number spawned |

## Age/Length Data

Ages of sockeye were determined from scales and otoliths collected from broodstock. The 2008 return was comprised primarily of age-4 returning adults ( $95.0 \%$; Table 4.2). Age-5 and 6 sockeye made up $4.0 \%$ and $1.0 \%$ of the 2008 return, respectively. The 2009 return consisted primarily of age-4 adults ( $78.5 \%$; Table 4.2 ). Age- 5 sockeye made up $21.5 \%$ of the 2009 return, respectively.
Table 4.2. Percent of hatchery and wild sockeye salmon of different ages (total age) collected from broodstock, 1994-2009.

| Return year | Origin | Total age |  |  |

## Sex Ratios

Male sockeye in the 2008 return made up about $49 \%$ of the adults collected, resulting in an overall male to female ratio of 0.97:1.00 (Table 4.4). In 2009, males made up about $51 \%$ of the adults collected, resulting in an overall male to female ratio of 1.04:1.00. Ratios for both years were near the $1: 1$ ratio target in the broodstock protocol.

Table 4.4. Numbers of male and female wild and hatchery sockeye collected for broodstock, 1989-2009. Ratios of males to females are also provided.

| Return year | Number of wild sockeye |  |  | Number of hatchery sockeye |  |  | Total M/F <br> ratio |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |

## Fecundity

Fecundities for the 2008 and 2009 returns of sockeye salmon averaged 2,555 and 2,459 eggs per female, respectively (Table 4.5). The lower mean fecundity for the 2009 return was likely because of the strong age- 4 component in the return. Fecundities for this program between 1989 and 2006 are based upon the total (pooled) number of eyed eggs divided by the number of females spawned. For brood years 2007 to present, mean fecundities were derived from individual fecundities.

Table 4.5. Mean fecundity of female sockeye salmon collected for broodstock, 1989-2009. Fecundities were determined from pooled egg lots and were not identified for individual females.

| Return year | Mean fecundity |
| :---: | :---: |
| 1989 | 2,344 |
| 1990 | 2,225 |
| 1991 | 2,598 |
| 1992 | 2,341 |

| Average | 2,628 |

### 4.2 Hatchery Rearing

## Rearing History

## Number of eggs taken

Based on the unfertilized egg-to-release survival standard of $81 \%$, a total of 246,914 eggs are required to meet the program release goal of 200,000 smolts. From 1989 to 2009, the egg take goal was reached in $59 \%$ of the years (Table 4.6). The number of eggs taken in 2010 was above the egg take target by $13 \%$.
Table 4.6. Numbers of eggs taken from sockeye broodstock, 1989-2010.

| Return year | Number of eggs taken |
| :---: | :---: |
| 1989 | 133,600 |
| 1990 | 326,267 |
| 1991 | 231,254 |
| 1992 | 381,561 |
| 1993 | 231,700 |

## Number of acclimation days

Wenatchee sockeye have only been acclimated on Lake Wenatchee water. For brood years 1989 through 1998, unfed fry were transferred from Eastbank FH to Lake Wenatchee Net Pens until release (Table 4.7). For brood years 1999 to present, juvenile sockeye were reared at Eastbank Fish Hatchery until July in an effort to increase growth before release.
Table 4.7. Water source and mean acclimation period for Wenatchee sockeye, brood years 1989-2008.

| Brood year | Release year | Transfer date | Release date | Number of Days | Water source |
| :---: | :---: | :---: | :---: | :---: | :---: |

## Release Information

## Numbers released

The 2008 Wenatchee sockeye program achieved $113.9 \%$ of the 200,000 target goal with about 227,743 fish being released (Table 4.8).

Table 4.8. Total number of sockeye parr released and numbers of released fish with CWTs and PIT tags for brood years 1989-2008. The release target for sockeye is 200,000 fish.

| Brood year | Release year | CWT mark rate | Number of released fish with PIT tags | Number released |
| :---: | :---: | :---: | :---: | :---: |
| 1989 | 1990 | Not marked | 0 | 108,400 |

| Average |  | 0.9355 | $14,769^{\text {b }}$ | 208,271 |

${ }^{\text {a }}$ These groups were only adipose fin clipped.
${ }^{\text {b }}$ Average is based on brood years 2005 to present.

## Numbers tagged

About $98 \%$ of the hatchery sockeye released in 2010 were CWT and adipose fin clipped (Table 4.8). In addition, a total of 15,102 juvenile sockeye were PIT tagged at the Eastbank Hatchery during 28 June to 1 July 2010. These fish were transported to the Lake Wenatchee net pens in July and released into the lake on 28 October 2010. At the time of release, a total of 609 fish had died and seven others had shed their tags. Thus, the total number of PIT-tagged sockeye released into the lake was 14,486 (Table 4.8).

## Fish size and condition at release

The 2008 brood sockeye were released as parr in 2009 and emigrated as yearling smolts in spring of 2010. Size at release was $3.8 \%$ and $52.4 \%$ of the fork length and weight goals, respectively. The 2008 brood year was also above the CV goal for length by $6.7 \%$ (Table 4.9).
Table 4.9. Mean lengths (FL, mm), weight ( g and fish/pound), and coefficient of variation (CV) of sockeye released, brood years 1989-2008. Size targets are provided in the last row of the table.

## Survival Estimates

Overall survival of Wenatchee sockeye from green (unfertilized) egg to release was above the standard set for the program. Survivals for unfertilized-to-eyed egg were well below the standard for the program. Because of the highly variable unfertilized-to-eyed egg survivals, studies should be considered that assess the effects of holding adults on warm surface water at Lake Wenatchee on gamete maturation/viability in addition to reducing negative phototactic behavior at swim up (potential influences on survival at the fertilization to ponding stages) (Table 4.10).

Table 4.10. Hatchery life-stage survival rates (\%) for sockeye salmon, brood years 1989-2008. Survival standards or targets are provided in the last row of the table.

| Brood <br> year | Collection to <br> spawning |  | Unfertilized <br> egg-eyed | Eyed <br> egg- <br> ponding | $\mathbf{3 0 d}$ <br> after <br> ponding | $\mathbf{1 0 0 d}$ <br> after <br> ponding | Ponding <br> to <br> release | Transport <br> to release | Unfertilized <br> egg-release |

### 4.3 Disease Monitoring

Rearing of the 2008 brood sockeye was typical to previous years with fish being held on Lake Wenatchee water in net pens for 100 days before being released directly into the lake. No significant disease-related mortality occurred during the rearing of the 2008 brood sockeye.

### 4.4 Natural Juvenile Productivity

During 2010, juvenile sockeye salmon were sampled at the Upper Wenatchee and Lower Wenatchee traps.

## Emigrant and Smolt Estimates

## Upper Wenatchee Trap

The Upper Wenatchee Trap operated nightly between 12 March and 8 July 2010. During the five-month sampling period, a total of 60,792 wild sockeye and 1,909 hatchery sockeye smolts were captured at the Upper Wenatchee Trap. Based on a pooled daily trap efficiency of $0.53 \%$ for both wild and hatchery sockeye (based on eight mark-recapture trials), the total number of smolts that emigrated past the trap in 2010 was $11,551,430( \pm 805,182)$ wild and 368,600 $( \pm 30,120)$ hatchery sockeye (Table 4.11). This was the fourth brood year since 1999 that all hatchery sockeye parr were released at a similar size and time. Monthly captures of all fish and results of capture efficiency tests at the Upper Wenatchee Trap are reported in Appendix B.
Because the estimated hatchery smolt number $(368,600)$ was greater than the actual number of hatchery parr released $(154,772)$, we adjusted our emigrant estimate and assumed that survival was $100 \%$ (Tables 4.11 and 4.14 ). Overestimation of the smolt migration is likely due to an underestimate of actual trap efficiency and probability of trap avoidance.
Table 4.11. Estimated numbers of wild and hatchery sockeye smolts that emigrated from Lake Wenatchee during run years 1997-2010.

| Run year | Numbers of sockeye smolts |  |
| :---: | :---: | :---: |
|  | Wild smolts | Hatchery smolts |
| 1997 | 55,359 | 28,828 |
| 1998 | $1,447,259$ | 55,985 |
| 1999 | $1,944,966$ | 112,524 |
| 2000 | 985,490 | 24,684 |
| 2001 | 39,353 | 94,046 |
| 2002 | 729,716 | 121,511 |

| Run year | Numbers of sockeye smolts |  |
| :---: | :---: | :---: |
|  | Wild smolts | Hatchery smolts |
| 2003 | $5,439,032$ | 140,322 |
| 2004 | $5,771,187$ | 216,023 |
| 2005 | 723,413 | 122,399 |
| 2006 | $1,266,971$ | 159,500 |
| 2007 | $2,797,313$ | 140,542 |
| 2008 | 549,682 | 102,907 |
| 2009 | 732,686 | 247,098 |
| 2010 | $11,551,430$ | 154,772 |
| Average | $\mathbf{2 , 4 3 0 , 9 9 0}$ | $\mathbf{1 2 2 , 9 3 9}$ |

Age classes of wild sockeye smolts were determined from a length frequency analysis based on scales collected randomly each year since 1997 (Table 4.12). For the available run years, most wild sockeye smolts migrated as age $1+$ fish. Only in two years (1997 and 2005) did more smolts migrate as age $2+$ fish. Relatively few smolts migrated at age $3+$.

Table 4.12. Age structure and estimated number of wild sockeye smolts that emigrated from Lake Wenatchee, 1997-2010.

| Run year | Proportion of wild smolts |  |  | Total wild emigrants |
| :---: | :---: | :---: | :---: | :---: |
|  | Age 1+ | Age 2+ | Age 3+ |  |
| 1997 | 0.075 | 0.906 | 0.019 | 55,359 |
| 1998 | 0.955 | 0.037 | 0.008 | $1,447,259$ |
| 1999 | 0.619 | 0.381 | 0.000 | $1,944,966$ |
| 2000 | 0.599 | 0.400 | 0.001 | 985,490 |
| 2001 | 0.943 | 0.051 | 0.006 | 39,353 |
| 2002 | 0.961 | 0.039 | 0.000 | 729,716 |
| 2003 | 0.740 | 0.026 | 0.000 | $5,439,032$ |
| 2004 | 0.929 | 0.071 | 0.000 | $5,771,187$ |
| 2005 | 0.230 | 0.748 | 0.022 | 723,413 |
| 2006 | 0.994 | 0.006 | 0.000 | $1,266,971$ |

| 2008 | 0.804 | 0.195 | 0.001 | 549,682 |
| 2009 | 0.930 | 0.055 | 0.051 | 732,686 |
| $2010^{*}$ | 0.975 | 0.024 | 0.001 | $11,551,430$ |
| Average | $\mathbf{0 . 7 6 8}$ | $\mathbf{0 . 2 1 0}$ | $\mathbf{0 . 0 0 8}$ | $\mathbf{2 , 4 3 0 , 9 9 0}$ |

* Ages have not been confirmed with scale analysis.

## Lower Wenatchee Trap

The Lower Wenatchee Trap operated nightly between 4 February and 20 July 2010. Because of high river flows, debris, snow/ice, or mechanical failure, traps 1 and 2 were inoperable for 19
and 68 days, respectively. During the six-month sampling period, a total of 3,153 wild sockeye smolts and 440 hatchery sockeye smolts were captured at the Lower Wenatchee Trap. Most of the smolts migrated during April and May. Monthly captures and mortalities of all fish collected at the Lower Wenatchee Trap are reported in Appendix B.

## Freshwater Productivity

Egg-smolt survival estimates for wild sockeye salmon are provided in Table 4.13. Estimates of egg deposition were calculated based on the spawner escapement at Tumwater Dam and the sex ratio and fecundity of the broodstock. Egg-smolt survival rates for brood years 1995-2007 have ranged from 0.012 to 0.212 (mean $=0.114$ ).

Table 4.13. Estimated egg deposition (estimated as mean fecundity times estimated number of females), numbers of smolts, and survival rates for wild Wenatchee sockeye salmon, 1995-2009; NA $=$ not available.

| Brood <br> year | Number of <br> females | Mean <br> fecundity | Total eggs |  | Numbers of wild smolts |  |  | Egg-smolt |

|  |  |  |  |  |  |  |  |  |

Juvenile survival rates for hatchery sockeye salmon are provided in Table 4.14. Release-smolt survival rates for brood years 1995-2008 have ranged from 0.000 to 1.000 (mean $=0.593$ ). Eggsmolt survival rates for the same brood years ranged from 0.000 to 0.817 (mean $=0.305$ ). On average, egg-smolt survival of hatchery sockeye is about three times greater than egg-smolt survival of wild sockeye. On four separate occasions, however, the estimated number of hatchery smolts equaled or exceeded the number of hatchery parr released in the lake. This is probably because the pooled trap efficiencies are biased high.

Table 4.14. Juvenile survival rates for hatchery Wenatchee sockeye, brood years 1995-2008.

| Brood year | Number of eggs | Number of parr released | Date of release | Estimated number of smolts | Egg-smolt survival | Release-smolt survival |

## PIT Tagging Activities

As part of the Integrated Status and Effectiveness Monitoring Program (ISEMP), a total of 10,006 juvenile sockeye salmon were PIT tagged and released in 2010 (Table 4.15a). All of these were tagged at the Upper Wenatchee Trap. No sockeye were tagged and released at the Lower Wenatchee trap. See Appendix C for a complete list of all fish captured, tagged, lost, and released.

Table 4.15a. Numbers of wild sockeye salmon that were captured, tagged, and released at different locations within the Wenatchee Basin, 2010. Numbers of fish that died or shed tags are also given.

| Sampling Location | Number held | Number of <br> recaptures | Number <br> tagged | Number died | Shed Tags | Total <br> released | Percent <br> mortality |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| Upper Wenatchee Trap | 11,103 | 7 | 10,082 | 76 | 0 | 10,006 | 0.68 |
| Lower Wenatchee Trap | 0 | 0 | 0 | 0 | 0 | 0 | -- |
| Total: | $\mathbf{1 1 , 1 0 3}$ | $\mathbf{7}$ | $\mathbf{1 0 , 0 8 2}$ | $\mathbf{7 6}$ | $\mathbf{0}$ | $\mathbf{1 0 , 0 0 6}$ | $\mathbf{0 6 8}$ |

Numbers of wild sockeye salmon PIT-tagged and released as part of ISEMP during the period 2006-2010 are shown in Table 4.15b.

Table 4.15b. Summary of the numbers of wild sockeye salmon that were tagged and released at different locations within the Wenatchee Basin, 2006-2010.

| Sampling Location | Numbers of PIT-tagged sockeye salmon released |  |  |  |  |

### 4.5 Spawning Surveys

Spawning surveys were conducted in the Little Wenatchee and White (including the Napeequa River) rivers from 24 August to 19 October 2010. Surveys in 2010 only included counting numbers of live sockeye spawners. No redd counts have been conducted since 2007 (see Appendix G for more details).

## Spawn Timing

Sockeye began spawning during the first week of September and peaked around the third week of September (Figure 4.1). Peak spawning was determined using the total number of spawners observed on the spawning grounds.

Figure 4.1. Numbers of sockeye spawners counted during different weeks in different sampling streams within the Wenatchee Basin, August through October 2010.

## Spawning Escapement

Spawning escapement of sockeye salmon in 2010 was estimated using the area-under-the-curve (AUC) method (i.e., escapement $=(\mathrm{AUC} /$ redd residence time $) \mathrm{x}$ observer efficiency) and markrecapture methods. AUC relied on weekly counts of live sockeye and assumed a redd residence time of 11 days and an observer efficiency of $100 \%$. The mark-recapture method used PIT tags to estimate sockeye spawning escapement (see Appendix G for more details).

## Area-under-the-curve

Based on the AUC approach, the estimated total spawning escapement of sockeye in the Wenatchee Basin in 2010 was 21,700 (Table 4.16). About $88 \%$ of the escapement spawned in the White River Basin (including the Napeequa River).
Table 4.16. Peak numbers of live spawners and total spawning escapement estimates for sockeye salmon in the Wenatchee Basin, August through October 2010.

| Sampling basin | Peak number of live fish | Spawning escapement |
| :---: | :---: | :---: |
| Little Wenatchee | 1,762 | 2,543 |
| White River | 11,380 | 19,157 |
| Total | $\mathbf{1 3 , 1 4 2}$ | $\mathbf{2 1 , 7 0 0}$ |

The spawning escapement of 7,767 Wenatchee sockeye is less than the overall average of 14,857 (Table 4.17).

Table 4.17. Spawning escapements for sockeye salmon in the Wenatchee Basin for return years 19892010; NA = not available. Total escapements before 2003 were based on counts at Tumwater Dam.

| Return year | Spawning escapement |  |  |
| :---: | :---: | :---: | :---: |

| 2008 | 3,491 | 16,757 | 20,248 |
| 2009 | 763 | 7,004 | 7,767 |
| 2010 | 2,543 | 19,157 | 21,700 |
| Average | 1,504 | 10,054 | 15,168 |

## Mark-recapture method

Using mark-recapture methods, the estimated total escapement of sockeye in the Upper Wenatchee Basin in 2010 was 21,604 (Table 4.18). About $90 \%$ of the escapement entered the White River Basin (including the Napeequa River).
Table 4.18. Estimated escapement of adult sockeye into the Little Wenatchee and White River basins for return years 2009-2010. Escapement is based on recapture of PIT tagged fish.

### 4.6 Carcass Surveys

Carcass surveys were conducted in the Little Wenatchee and White (including the Napeequa River) rivers from 15 September to 25 October 2010.

## Number sampled

A total of 8,119 sockeye carcasses were sampled during September through October, 2010, in the Wenatchee Basin (Table 4.19). This is considerably higher than the 1993-2010 average of 2,832 carcasses. Most of the carcasses sampled in 2010 were collected in the White River basin ( $97 \%$ or 7,902 carcasses) (Figure 4.2). The remaining $3 \%$ were sampled in the Little Wenatchee River (217 carcasses).
Table 4.19. Numbers of sockeye carcasses sampled within different streams/watersheds within the Wenatchee Basin, 1989-2010.

| Survey year | Numbers of sockeye carcasses |  |  |  |

| 2010 | 217 | 7,832 | 70 | 8,119 |
| Average | 223 | 2,576 | 33 | 2,832 |

Figure 4.2. Percent of the peak number of live sockeye observed and the total number of sockeye carcasses sampled in different streams/watersheds within the Wenatchee Basin during August through October, 2010.

## Carcass Distribution and Origin

Sockeye carcasses were not evenly distributed among reaches within survey streams in 2010 (Table 4.20). Carcasses were only found in Reaches 2 (Lost Creek to Rainy Creek) on the Little Wenatchee. Most (99\%) of the carcasses sampled in the White River Basin were in Reach 2 (Sears Creek Bridge to Napeequa River). About 1\% of the carcasses sampled in the White River Basin were in the Napeequa River.
Table 4.20. Numbers of carcasses sampled within different streams/watersheds within the Wenatchee Basin during August through September, 2010.

| Stream/watershed | Reach | Total carcasses |
| :---: | :---: | :---: |
| Little Wenatchee | Little Wen 1 | 0 |
|  | Little Wen 2 | 217 |
|  | Little Wen 3 | 0 |
|  | Total | 217 |
| White | White 1 | 0 |
|  | White 2 | 7,832 |
|  | White 3 | 0 |
|  | Napeequa 1 | 70 |
|  | Total | 7,902 |
| Grand Total |  | 8,119 |

Numbers of wild and hatchery-origin sockeye carcasses sampled in 2010 will be available after analysis of marks/tags and scales. Based on the available data (1993-2009), the largest
percentage of both wild and hatchery sockeye spawned in Reach 2 on the White River (Table 4.21 and Figure 4.3). However, a greater percentage of wild fish were found in Reach 2 than hatchery fish. The opposite occurred in Reach 2 on the Little Wenatchee. There, a larger percentage of hatchery fish were found compared to wild fish.
Table 4.21. Numbers of wild and hatchery sockeye carcasses sampled within different reaches in the Wenatchee Basin, 1993-2010. Reach codes are described in Table 2.9.

Wenatchee Sockeye Salmon

Figure 4.3. Distribution of wild and hatchery produced carcasses in different reaches in the Wenatchee Basin, pooled data from 1993-2010. Reach codes are described in Table 2.9; $\mathrm{L}=$ Little Wenatchee, $\mathrm{H}=$ White River, and $\mathrm{Q}=$ Napeequa River.

## Sampling Rate

The sampling rate of sockeye carcasses differed among basins, with a higher sampling rate in the White than in the Little Wenatchee (Table 4.22). Nevertheless, the overall sampling rate for both basins combined exceeded the target of $20 \%$.
Table 4.22. Numbers of carcasses, estimated spawning escapements (based on AUC), and sampling rates for sockeye salmon in the Wenatchee Basin, 2010.

| Sampling basin | Total number of carcasses | Total spawning escapement | Sampling rate |
| :---: | :---: | :---: | :---: |
| Little Wenatchee | 217 | 2,543 | 0.09 |
| White | 7,902 | 19,157 | 0.41 |
| Total | 8,119 | 21,700 | 0.37 |

## Length Data

Mean lengths ( $\mathrm{POH}, \mathrm{cm}$ ) of male and female hatchery sockeye carcasses sampled during surveys in the Wenatchee Basin in 2010 are provided in Table 4.23. Wild sockeye are sampled at Tumwater Dam, not on the spawning grounds. On average, males were slightly larger than females.

Table 4.23. Mean lengths (postorbital-to-hypural length; cm ) and standard deviations (in parentheses) of male and female hatchery sockeye carcasses sampled in different streams/watersheds in the Wenatchee Basin, 2010; $\mathrm{N}=$ number of fish sampled. Wild sockeye were sampled at Tumwater Dam.

| Stream/watershed |  | Male |  | Female |  |
| :--- | :---: | :---: | :---: | :---: | :---: |
|  |  | Length (cm) | $\mathbf{N}$ | Length (cm) |  |

| Wenatchee River | 0 | NA | 0 | NA |  |
| $\boldsymbol{T o t a l}$ | $\mathbf{4 3}$ | $\mathbf{4 1 . 7}(\mathbf{2 . 1})$ | $\mathbf{8 7}$ | $\mathbf{4 0 . 6}(\mathbf{1 . 8})$ |  |

### 4.7 Life History Monitoring

Life history characteristics of Wenatchee sockeye were assessed by examining carcasses on spawning grounds and fish sampled at broodstock collection sites, and by reviewing tagging data and fisheries statistics.

## Migration Timing

There was little difference in migration timing of hatchery and wild sockeye past Tumwater Dam (Table 4.24a and b; Figure 4.4). On average, early in the run, hatchery and wild sockeye arrived at the dam at about the same time. Toward the end of the migration period, hatchery sockeye tended to arrive at the dam slightly later than did wild sockeye. Most hatchery and wild sockeye migrated upstream past Tumwater Dam during July through early August. The peak migration time for both hatchery and wild sockeye was the last week of July (Figure 4.4).
Table 4.24a. The Julian day and date that $10 \%, 50 \%$ (median), and $90 \%$ of the wild and hatchery sockeye salmon passed Tumwater Dam, 1998-2010. The average Julian day and date are also provided. Migration timing is based on video sampling at Tumwater. Data for 1998 through 2003 were based on videotapes and broodstock trapping and may not reflect the actual number of hatchery sockeye salmon. All sockeye were visually examined during trapping from 2004 to present.

| Survey year | Origin | Sockeye Migration Time (days) |  |  |  |  |  |  |  | Sample size |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  |  | 10 Percentile |  | 50 Percentile |  | 90 Percentile |  | Mean |  |  |
|  |  | Julian | Date | Julian | Date | Julian | Date | Julian | Date |  |

Table 4.24b. The week that $10 \%, 50 \%$ (median), and $90 \%$ of the wild and hatchery sockeye salmon passed Tumwater Dam, 1998-2010. The average week is also provided. Migration timing is based on video sampling at Tumwater. Data for 1998 through 2003 were based on videotapes and broodstock trapping and may not reflect the actual number of hatchery sockeye salmon. All sockeye were visually examined during trapping from 2004 to present.

## Sockeye Migration Timing

Migration Week
Figure 4.4. Proportion of wild and hatchery sockeye observed (using video) passing Tumwater Dam each week during their migration period late-June through early-October; data were pooled over survey years 1998-2010.

## Age at Maturity

Although sample sizes are small, it appears that most wild sockeye returned as age- 5 fish, while most hatchery sockeye returned as age-4 fish (Table 4.25; Figure 4.5). Only wild fish have returned at age-6.

Table 4.25. Proportions of wild and hatchery sockeye of different ages (total age) sampled in broodstock and on spawning grounds, 1994-2009.

## Sockeye Age Structure

Figure 4.5. Proportions of wild and hatchery sockeye salmon of different total ages sampled at Tumwater Dam and on spawning grounds in the Wenatchee Basin for the combined years 1994-2009.

## Size at Maturity

Although sample sizes are small, wild sockeye were larger than hatchery sockeye in 2009 (Table 4.26). This is because more wild fish return at age 5, while more hatchery fish return at age 4 . However, the pooled data indicate that there is virtually no difference in mean sizes of hatchery and wild sockeye salmon sampled in the Wenatchee Basin (Table 4.26). Future analyses will compare sizes of hatchery and wild fish of the same age groups and gender.
Table 4.26. Mean lengths ( $\mathrm{POH} ; \mathrm{cm}$ ) and variability statistics for wild and hatchery sockeye salmon sampled at Tumwater Dam (broodstock) and on spawning grounds in the Wenatchee Basin, 1994-2009; SD $=1$ standard deviation.

## Contribution to Fisheries

The total number of hatchery and wild sockeye captured in different fisheries is provided in Tables 4.27 and 4.28. Harvest on hatchery-origin sockeye has been less than the harvest on wild sockeye.

Table 4.27. Estimated number and percent (in parentheses) of hatchery-origin Wenatchee sockeye captured in different fisheries, 1989-2004.

${ }^{\text {a }}$ Includes the Lake Wenatchee fishery.

## Straying

Stray rates were determined by examining CWTs recovered on spawning grounds within and outside the Wenatchee Basin. Targets for strays based on return year (recovery year) outside the Wenatchee Basin should be less than 5\%. The target for brood year strays should also be less than 5\%.

There is no record that hatchery-origin Wenatchee sockeye have strayed into other spawning areas outside the Wenatchee Basin. This may be related to the lack of carcass surveys in other locations. Nevertheless, the existing data indicate that hatchery-origin sockeye stray at a rates less than the target of $5 \%$.
Based on brood year analysis, virtually no hatchery-origin Wenatchee sockeye have strayed into non-target spawning areas or hatchery programs (Table 4.29). These data indicate that hatcheryorigin Wenatchee sockeye stray at rates less than the target of $5 \%$.

Table 4.29. Number and percent of hatchery-origin Wenatchee sockeye that homed to target spawning areas and the target hatchery program, and number and percent that strayed to non-target spawning areas and hatchery programs, by brood years 1990-2004. Hatchery-origin sockeye from brood years 1995-1998 were not tagged because of columnaris disease. Percent stays should be less than 5\%.

| Brood year | Homing |  |  |  | Straying |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |

## Genetics

Genetic studies were conducted to determine the potential impacts of the Wenatchee sockeye supplementation program on natural-origin sockeye in the upper Wenatchee Basin (Blankenship et al. 2008; the entire report is appended as Appendix H). Specifically, the objective of the study was to determine if the genetic composition of the Lake Wenatchee sockeye population had been altered by the supplementation program, which was based on the artificial propagation of a small subset of the Wenatchee population. Microsatellite DNA allele frequencies were used to differentiate between temporally replicated collections of natural and hatchery-origin sockeye in the Wenatchee Basin. A total of 13 collections of Wenatchee sockeye were analyzed; eight temporally replicated collections of natural-origin sockeye and five temporally replicated collections of hatchery-origin sockeye. Paired natural-hatchery collections were available from return years 2000, 2001, 2004, 2006, and 2007.
Overall, the study showed that allele frequency distributions were consistent over time, regardless of origin, resulting in small, insignificant measures of genetic differentiation among collections. This indicates that there was no year-to-year differences in allele frequencies between natural and hatchery-origin sockeye. In addition, the analyses found no differences
between pre- and post-supplementation collections. Thus, it was concluded that the allele frequencies of the broodstock collections equaled the allele frequency of the natural collections.

## Proportion of Natural Influence

Another method for assessing the genetic risk of a supplementation program is to determine the influence of the hatchery and natural environments on the adaptation of the composite population. This is estimated by the proportion of natural-origin fish in the hatchery broodstock ( pNOB ) and the proportion of hatchery-origin fish in the natural spawning escapement ( pHOS ). The ratio $\mathrm{pNOB} /(\mathrm{pHOS}+\mathrm{pNOB})$ is the Proportion of Natural Influence (PNI). The larger the ratio ( PNI ), the greater the strength of selection in the natural environment relative to that of the hatchery environment. In order for the natural environment to dominate selection, PNI should be greater than 0.5 (HSRG/WDFW/NWIFC 2004).

For brood years 1989-2008, the PNI was consistently been greater than 0.5 (Table 4.30). This indicates that the natural environment has a greater influence on adaptation of Wenatchee sockeye than does the hatchery environment.

Table 4.30. Proportionate natural influence (PNI) of the Wenatchee sockeye supplementation program for brood years 1989-2008. PNI was calculated as the proportion of naturally produced sockeye in the hatchery broodstock ( pNOB ) divided by the proportion of hatchery sockeye counted at Tumwater Dam ( pHOS ) plus pNOB. NOS = number of natural-origin sockeye counted at Tumwater Dam; HOS = number of hatchery-origin sockeye counted at Tumwater Dam; NOB = number of natural-origin sockeye collected for broodstock; and $\mathrm{HOB}=$ number of hatchery-origin sockeye included in hatchery broodstock.

${ }^{\text {a }}$ Proportions of natural-origin and hatchery-origin spawners were determined from video tape at Tumwater Dam.

## Natural Replacement Rates

Natural replacement rates (NRR) were calculated as the ratio of natural-origin recruits (NOR) to the parent spawning population. For brood years 1989-2004, NRR in the Wenatchee averaged 1.17 (range, 0.13-4.28) if harvested fish were not included in the estimate and 1.34 (range, 0.144.78) if harvested fish were included in the estimate (Table 4.31).

Hatchery replacement rates (HRR) were estimated as hatchery adult-to-adult returns. These rates should be greater than the NRRs and greater than or equal to 5.40 (the calculated target value in Murdoch and Peven 2005). HRRs exceeded NRRs in nine of the 16 years of data, regardless if harvest was or was not included in the estimates (Table 4.31). Hatchery replacement rates for Wenatchee sockeye have equaled or exceeded the estimated target value of 5.40 in only three years regardless if harvest was or was not included in the estimate (Table 4.31).
Table 4.31. Broodstock collected, spawning escapements, natural and hatchery-origin recruits (NOR and HOR), and natural and hatchery replacement rates (NRR and HRR; with and without harvest) for sockeye salmon in the Wenatchee Basin, 1989-2004.

| Brood year | Broodstock Collected | Spawning Escapement | Harvest not included |  |  |  | Harvest included |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  |  |  | HOR | NOR | HRR | NRR | HOR | NOR | HRR | NRR |

## Juvenile-to-Adult Survivals

When possible, both parr-to-adult ratios (PAR) and smolt-to-adult ratios (SAR) were calculated for hatchery sockeye salmon. Ratios were calculated as the number of hatchery adult recaptures divided by the number of tagged hatchery parr released or the estimated number of smolts emigrating from Lake Wenatchee. Survival ratios were based on CWT returns, when available, or on the estimated number of hatchery adults recovered on the spawning grounds, in broodstock, and harvested. For the available brood years, PARs have ranged from 0.0001 to 0.0143 for hatchery sockeye salmon and SARs have ranged from 0.0002 to 0.0258 (Table 4.32).

Table 4.32. Parr-to-adult ratios (PAR) and smolt-to-adult ratios (SAR) for Wenatchee hatchery sockeye salmon, brood years 1990-2003; NA = not available.

| Brood year | Number of parr released | Number of smolts | Estimated adult recaptures | PAR | SAR |

### 4.8 ESA/HCP Compliance

## Broodstock Collection

The 2008 sockeye broodstock collections at Tumwater Dam occurred concurrently with the spring Chinook reproductive success monitoring and evaluation activities (BPA Project No. 2003-039-00) and Wenatchee steelhead broodstock collection activities authorized under ESA permits 1196 and 1395, respectively. No ESA-listed spring Chinook or steelhead take occurred during sockeye broodstock collections at Tumwater Dam that were outside those authorized through ESA Section 10 permits 1196 and 1395.

## Hatchery Rearing and Release

The 2008 Wenatchee sockeye program released 154,772 juveniles, representing $77 \%$ of the program production objective production overage allowance in ESA Section 10 Permit 1347.

## Hatchery Effluent Monitoring

Per ESA Permits 1196, 1347, and 1395, permit holders shall monitor and report hatchery effluents in compliance with applicable National Pollution Discharge Elimination Systems (NPDES) (EPA 1999) permit limitations. NPDES monitoring and reporting for Chelan PUD Hatchery Programs during 2010 are provided in Appendix E.

## Smolt and Emigrant Trapping

ESA-listed spring Chinook and steelhead were encountered during operation of the upper and lower Wenatchee traps. ESA takes are reported in the steelhead (Section 3.8) and spring Chinook (Section 5.8) sections and will not be repeated here.

## Spawning Surveys

Sockeye spawning ground surveys conducted in the Wenatchee Basin during 2010 were consistent with ESA Section 10 Permit No. 1347. Because of the difficulty of quantifying the level of take associated with spawning ground surveys, the Permit does not specify a take level associated with these activities, even though it does authorize implementation of spawning ground surveys. Therefore, no take levels are reported. However, to minimize potential impacts to established redds, wading was restricted to the extent practical and extreme caution was used to avoid established redds when wading was required.

## SECTION 5: WENATCHEE (CHIWAWA) SPRING CHINOOK

Although this section of the report focuses on results from monitoring the Chiwawa spring Chinook program, information on spring Chinook collected throughout the Wenatchee Basin is also provided.

### 5.1 Broodstock Sampling

This section focuses on results from sampling 2008-2010 Chiwawa spring Chinook broodstock, which were collected at the Chiwawa weir and at Tumwater Dam. Some information for the 2010 return is not available at this time (e.g., age structure and final origin determination). This information will be provided in the 2011 annual report.

## Origin of Broodstock

Hatchery-origin adults made up between $55-73 \%$ of the Chiwawa spring Chinook broodstock for return years 2008-2010 (Table 5.1). Hatchery-origin adults were collected at both Tumwater Dam and the Chiwawa weir. In an effort to partially address straying of Chiwawa spring Chinook to other tributaries in the basin, and secondarily to ensure meeting adult collection quotas, hatchery-origin adults were collected to the greatest extent possible at Tumwater Dam. Natural-origin fish were collected only at the Chiwawa weir. Broodstock were trapped at Tumwater Dam and Chiwawa weir from mid-June through August.
Table 5.1. Numbers of wild and hatchery Chiwawa spring Chinook collected for broodstock, numbers that died before spawning, and numbers of Chinook spawned, 1989-2010. Unknown origin fish (i.e., undetermined by scale analysis, no CWT or fin clips, and no additional hatchery marks) were considered naturally produced. Mortality includes fish that died of natural causes typically near the end of spawning and were not needed for the program or were surplus fish killed at spawning.

| Brood year | Wild spring Chinook |  |  |  |  | Hatchery spring Chinook |  |  |  |  | Total number spawned |

${ }^{\text {a }}$ Origin determinations should be considered preliminary pending scale analyses.

## Age/Length Data

Ages were determined from scales and/or coded wire tags (CWT) collected from broodstock. For both the 2008 and 2009 returns, most adults, regardless of origin, were age- 4 Chinook (Table 5.2). A larger percentage of the age-5 Chinook were natural-origin fish, whereas a larger percentage of the age- 3 fish were hatchery-origin fish.
Table 5.2. Percent of hatchery and wild spring Chinook of different ages (total age) collected from broodstock, 1991-2009.

| Return year | Origin | Total age |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: |

There was little difference in mean lengths between hatchery and natural-origin broodstock of age-4 and 5 Chinook in 2008 and 2009 (Table 5.3). Additionally, for the 2008 and 2009 returns, there was relatively little difference in mean lengths within or among years for age- 3 hatchery and natural-origin fish.

## Sex Ratios

Male spring Chinook in 2008-2010 return years made up $46 \%$, $50 \%$, and $51 \%$, respectively, of the adults collected. This resulted in overall male to female ratios of 0.84:1.00, 1.00:1.00, and 1.02:1.00, respectively (Table 5.4). Only returns in 2009 and 2010 were ratios at or above the $1: 1$ target in the broodstock protocol. For the 2010 return year, natural-origin fish consisted of a slightly lower proportion of males than females, whereas hatchery-origin fish consisted of a slightly higher proportion of males than females (Table 5.4.).

Table 5.4. Numbers of male and female wild and hatchery spring Chinook collected for broodstock, 1989-2010. Ratios of males to females are also provided.

| Return year | Number of wild spring Chinook |  |  | Number of hatchery spring Chinook |  |  | Total M/F ratio |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |

## Fecundity

Mean fecundities for the 2008-2010 returns of spring Chinook ranged from 4,314-4,592 eggs per female (Table 5.5). These fecundities were less than the overall average of 4,825 eggs per female, but were close to the expected fecundity of 4,400 eggs per female assumed in the broodstock protocol. For the three return years, natural-origin Chinook produced more eggs per female than did hatchery-origin fish (Table 5.5). This could be attributed to differences in size and age of hatchery and natural-origin fish described above.

Table 5.5. Mean fecundity of wild, hatchery, and all female spring Chinook collected for broodstock, 1989-2010; NA = not available.

| Return year | Mean fecundity |  |  |

| 2009 | 4,691 | 4,487 | 4,573 |
| 2010 | 4,548 | 4,114 | 4,314 |
| Average | 4,866 | 4,630 | 4,825 |

* Individual fecundities were not tracked with females until 1997.
${ }^{\text {a }}$ Estimated as the mean of fecundities two years before and two years after 1992.

### 5.2 Hatchery Rearing

## Rearing History

## Number of eggs taken

Based on the unfertilized egg-to-release survival standard of $81 \%$, a total of 829,630 eggs are required to meet the program release goal of 672,000 smolts. Between 1989 and 2010, the egg take goal was reached in one of those years (Table 5.6). The green egg takes for 2008-2010 brood years were $92 \%, 68 \%$, and $46 \%$ of program goals, respectively.
ESA Permit 1196 sets limits on the percentage of the total run, natural-origin run, and a minimum contribution of natural-origin fish that must be in the broodstock. Applying these criteria to the low total abundance of spring Chinook salmon to the Chiwawa Basin and the low
abundance of natural-origin fish returning to the basin has resulted in the program not meeting production goals.
Table 5.6. Numbers of eggs taken from spring Chinook broodstock, 1989-2010.

| Return year | Number of eggs taken |
| :---: | :---: |
| 1989 | 45,311 |

## Number of acclimation days

Early rearing of the 2008 brood Chiwawa spring Chinook was similar to previous years with fish being held on well water before being transferred to Chiwawa Ponds for final acclimation. Beginning in 2006 (2005 brood acclimation), modifications were made to the Chiwawa Fish Hatchery intakes so that Wenatchee River water could be applied to the Chiwawa River intakes during severe cold periods to prevent the formation of frazzle ice. During acclimation of the 2008 brood, fish were acclimated for 212 to 241 days on Chiwawa River water, with 129 of those days containing a small percentage of Wenatchee River water to prevent freezing of hatchery intakes (Table 5.7).

Table 5.7. Number of days spring Chinook broods were acclimated and water source, brood years 19892008; NA = not available.

| Brood year | Release year | Transfer date | Release date | Number of days and water source |  |  |

${ }^{\text {a }}$ Represents the number of days Wenatchee River water was applied to the Chiwawa River intake screen to prevent the formation of frazzle ice.

## Release Information

## Numbers released

The 2008 brood Chiwawa spring Chinook program achieved $90.7 \%$ of the 672,000 target goal with about 609,789 smolts being released volitionally into the Chiwawa River (Table 5.8).

Table 5.8. Numbers of spring Chinook smolts tagged and released from the hatchery, brood years 19892008. The release target for Chiwawa spring Chinook is 672,000 smolts.

| Brood year | Release year | Type of release | CWT mark rate | Number released that were PIT tagged | Number of smolts released | Total number of smolts released |

${ }^{\text {a }}$ This does not include the 226,456 eyed eggs that were planted in the Chiwawa River.
${ }^{\mathrm{b}}$ This high ELISA group was only adipose fin clipped and directly planted into Big Meadow Creek in May.

## Numbers tagged

The 2008 brood Chiwawa spring Chinook were $98.4 \%$ CWT and adipose fin clipped (Table 5.8).

In 2010, a total of 10,101 spring Chinook from the 2009 brood were PIT tagged at the Eastbank Hatchery during 8-10 June. These fish were transferred to the Chiwawa raceway in September. As of the end of January 2011, a total of 442 tagged fish have died and four others have shed their tags, leaving 9,655 tagged spring Chinook alive. These fish will be released in the Chiwawa River in spring of 2011. Table 5.9 summarizes the number of hatchery spring Chinook that have been PIT-tagged and released into the Chiwawa River.
Table 5.9. Summary of PIT-tagging activities for Chiwawa hatchery spring Chinook, brood years 20052008.

| Brood year | Release year | Number of fish <br> tagged | Number of <br> tagged fish that <br> died | Number of tags <br> shed | Number of <br> tagged fish <br> released |

| 2008 | 2010 | 10,101 | 81 | 14 | 10,006 |

${ }^{\text {a }}$ This release consisted of 4,988 tagged Chinook that were released volitionally and 4,993 that were forced released.

## Fish size and condition at release

Spring Chinook from the 2008 brood were released as yearling smolts between 14 April and 15 May 2010. Size at release was below the targets established for the program. The coefficient of variation for fork length was $19 \%$ above the target (Table 5.10).
Table 5.10. Mean lengths (FL, mm), weight ( g and fish/pound), and coefficient of variation (CV) of spring Chinook smolts released from the hatchery, brood years 1989-2008. Size targets are provided in the last row of the table.

## Survival Estimates

Overall survival of Chiwawa spring Chinook from green (unfertilized) egg to release was slightly below the standard set for the program (Table 5.11). Survival from the eyed egg-toponding stage was slightly below program objectives. Pre-spawn survival of adults was above the standard set for the program.
Table 5.11. Hatchery life-stage survival rates (\%) for spring Chinook, brood years 1989-2008. Survival standards or targets are provided in the last row of the table.

| Brood year | Collection to spawning |  | Unfertilized egg-eyed | $\begin{gathered} \text { Eyed } \\ \text { egg- } \\ \text { ponding } \end{gathered}$ |  | $100 \mathrm{~d}$afterponding | Ponding to release | Transport to release | Unfertilized egg-release |

### 5.3 Disease Monitoring

Results of 2010 adult broodstock bacterial kidney disease (BKD) monitoring indicated that most females ( $95.6 \%$ ) had ELISA values less than 0.199. About 95\% of females had ELISA values less than 0.120 , which would have required about $5 \%$ of the progeny to be reared at densities not to exceed 0.06 fish per pound (Table 5.12). As per the HCP Hatchery Committee Agreement, progeny from the four high ELISA females were culled to minimize possible negative effects to the balance of the program. These progeny represented about $7 \%$ of the estimated production for the 2010 brood.

Mortalities resulting from external fungal infections began increasing shortly after transfer to the Chiwawa Ponds. The first formalin drip treatment failed to control the infection. The failure precipitated a second treatment, which was successful. No significant health issues were encountered for the remainder of juvenile rearing.
Table 5.12. Proportion of bacterial kidney disease (BKD) titer groups for the Chiwawa spring Chinook broodstock, brood years 1996-2010. Also included are the proportions to be reared at either 0.125 fish per pound or 0.060 fish per pound.

### 5.4 Natural Juvenile Productivity

During 2010, juvenile spring Chinook were sampled at the Upper Wenatchee, Lower Wenatchee, and Chiwawa traps and counted during snorkel surveys within the Chiwawa Basin.

## Parr Estimates

A total of $128,220( \pm 14 \%)$ subyearling and $291( \pm 31 \%)$ yearling spring Chinook were estimated in the Chiwawa River Basin in August 2010 (Table 5.13 and 5.14). During the survey period 1992-2010, numbers of subyearling and yearling Chinook have ranged from 5,815 to 134,872 and 5 to 563, respectively, in the Chiwawa Basin (Table 5.13 and 5.14; Figure 5.1). Numbers of all fish counted in the Chiwawa Basin are reported in Appendix A.

Table 5.13. Total numbers of subyearling spring Chinook estimated in different steams in the Chiwawa Basin during snorkel surveys in August 1992-2010; NS = not sampled.

Figure 5.1. Numbers of subyearling and yearling Chinook salmon within the Chiwawa River Basin in August 1992-2010; ND = no data.
Juvenile Chinook were distributed contagiously among reaches in the Chiwawa River. Their densities were highest in the upper portions of the basin, with the highest densities within tributaries. Juvenile Chinook were most abundant in multiple channels and least abundant in glides. Most Chinook associated closely with woody debris in multiple channels. These sites (multiple channels) made up $16 \%$ of the total area of the Chiwawa Basin, but they provided
habitat for $53 \%$ of all the subyearling Chinook in the basin in 2010. In contrast, riffles made up $53 \%$ of the total area, but provided habitat for only $11 \%$ of all juvenile Chinook in the Chiwawa Basin. Pools made up $23 \%$ of the total area and provided habitat for $34 \%$ of all juvenile Chinook in the basin. Virtually no Chinook used glides that lacked woody debris.
Mean densities of juvenile Chinook in two reaches of the Chiwawa River were generally less than those in corresponding reference areas (Nason Creek and the Little Wenatchee River) (Figure 5.2). Within both the Chiwawa River and its reference areas, pools and multiple channels consistently had the highest densities of juvenile Chinook.

Figure 5.2. Comparison of the 17-year means of subyearling spring Chinook densities within state/habitat types in reaches 3 and 8 of the Chiwawa River and their matched reference areas on Nason Creek and the Little Wenatchee River. $\mathrm{NC}=$ natural channel; $\mathrm{S}=$ straight channel; $\mathrm{EB}=$ eroded banks; $\mathrm{MC}=$ multiple channel. There was no sampling in 2000 and no sampling within reference areas in 1992.

## Smolt and Emigrant Estimates

Numbers of spring Chinook smolts and emigrants were estimated at the Upper Wenatchee, Chiwawa, and Lower Wenatchee traps in 2010.

## Chiwawa Trap

The Chiwawa Trap operated between 5 March and 22 November 2010. During that time period the trap was inoperable for 20 days because of high river flows, debris, snow/ice, mechanical failure, or furlough days. The trap operated in two different positions depending on stream flow; lower position at flows greater than $12 \mathrm{~m}^{3} / \mathrm{s}$ and an upper position at flows less than $12 \mathrm{~m}^{3} / \mathrm{s}$. Daily trap efficiencies were estimated from two regression models depending on trap position and age class of fish (e.g., subyearling and yearling). The daily number of fish captured was expanded by the estimated trap efficiency to estimate daily total emigration. Monthly captures of
all fish and results of mark-recapture efficiency tests at the Chiwawa Trap are reported in Appendix B.

Wild yearling spring Chinook (2008 brood year) were primarily captured from March through June 2010 (Figure 5.3). Based on capture efficiencies estimated from the flow model, the total number of wild yearling Chinook emigrating from the Chiwawa River was $35,023( \pm 9,438)$. Combining the total number of subyearling spring Chinook $(85,161)$ that emigrated during the fall of 2009 with the total number of yearling Chinook $(35,023)$ that emigrated during 2010 resulted in a total emigrant estimate of 120,184 spring Chinook for the 2008 brood year (Table 5.15).

Juvenile Spring Chinook

${ }^{\text {a }}$ The estimated number of smolts (yearlings) that are produced entirely within the Chiwawa Basin. Smolt estimates for brood years 1992-1996 were calculated with a mark-recapture model; brood years 1997-present were calculated with a flow model.
${ }^{\mathrm{b}}$ These numbers represent Chiwawa smolts produced within the entire Wenatchee Basin. This assumes that $66 \%$ of the subyearling migrants from the Chiwawa Basin survive to smolt in the Wenatchee Basin, regardless of the number of subyearling migrants (i.e., no density dependence). Smolt estimates for brood years 1992-1996 were calculated with a mark-recapture model; brood years 1997-present were calculated with a flow model.
${ }^{c}$ Estimate only includes numbers of Chinook in the Chiwawa River. Tributaries were not sampled at that time.

Wild subyearling spring Chinook (2009 brood year) were captured between 5 March and 22 November 2010. Based on capture efficiencies estimated from the flow model for both the upper trap position and lower position, the total number of wild subyearling (fry and parr) Chinook from the Chiwawa Basin was $103,185( \pm 15,166)$. Removing fry from the estimate, a total of $31,913( \pm 5,779)$ parr emigrated from the Chiwawa Basin in 2010. Although subyearlings migrated during most months of sampling, the majority ( $91 \%$ ) migrated during April, July, August, October, and November (Figure 5.3).
Yearling spring Chinook sampled in 2010 averaged 91 mm in length, 8.9 g in weight, and had a mean condition of 1.15 (Table 5.16). These size estimates were less than the overall mean of yearling spring Chinook sampled in previous years (overall means: $94 \mathrm{~mm}, 9.3 \mathrm{~g}$, and condition of 1.08). Subyearling spring Chinook sampled in 2010 at the Chiwawa Trap averaged 77 mm in length, averaged 5.4 g , and had a mean condition of 1.11 (Table 5.16). These sizes were similar to the overall mean of subyearling spring Chinook sampled in previous years (overall means, 77 $\mathrm{mm}, 5.6 \mathrm{~g}$, and condition of 1.09 ).

Table 5.16. Mean fork length (mm), weight (g), and condition factor of subyearling and yearling spring Chinook collected in the Chiwawa Trap, 1996-2010. Numbers in parentheses indicate 1 standard deviation.

| Sample year | Life stage | Sample size ${ }^{\text {a }}$ | Mean size |  |  |

${ }^{a}$ Sample size represents the number of fish that were measured for both length and weight.

## Upper Wenatchee Trap

The Upper Wenatchee Trap operated nightly between 12 March and 8 July 2010. During the five-month sampling period, a total of 569 wild yearling Chinook, 254 wild subyearling Chinook, and 245 hatchery yearling Chinook were captured at the Upper Wenatchee Trap. Monthly captures of all fish collected at the Upper Wenatchee Trap are reported in Appendix B.

## Lower Wenatchee Trap

The Lower Wenatchee Trap operated nightly between 4 February and 20 July 2010. During that time period the trap was inoperable for 19 days because of high river flows, debris, snow/ice, or mechanical failure. During the seven-month sampling period, a total of 1,079 wild yearling Chinook, 50,685 wild subyearling Chinook (mostly summer Chinook), and 43,613 hatchery yearling Chinook were captured at the Lower Wenatchee Trap. Based on capture efficiencies estimated from the flow model, the total number of wild yearling Chinook that emigrated past the Lower Wenatchee Trap was 82,137 ( $\pm 87,931$ ). The majority ( $59 \%$ ) of these fish emigrated during April. Monthly captures of all fish collected at the Lower Wenatchee Trap are reported in Appendix B.

## PIT Tagging Activities

As part of the Integrated Status and Effectiveness Monitoring Program (ISEMP), a total of 12,380 wild juvenile Chinook ( 4,689 subyearling and 7,691 yearlings) were PIT tagged and released in 2010 throughout the Wenatchee Basin (Table 5.17a). Most of these ( $82 \%$ ) were tagged in the Chiwawa Basin ( 9,605 at the trap plus 535 others upstream from the trap). Few were tagged and released in the Wenatchee River. A total of 917 Chinook were tagged and released at the Lower Wenatchee trap. See Appendix C for a complete list of all fish captured, tagged, lost, and released.

Table 5.17a. Numbers of wild Chinook that were captured, tagged, and released at different locations within the Wenatchee Basin, 2010. Numbers of fish that died or shed tags are also given.

## Freshwater Productivity

Both productivity and survival estimates for different life stages of spring Chinook in the Chiwawa Basin are provided in Table 5.18. Estimates for brood year 2008 fall within the ranges estimated over the period of brood years 1991-2007. During that period, freshwater productivities ranged from 125-1,015 parr/redd, 132-779 smolts/redd, and 174-834 emigrants/redd. Survivals during the same period ranged from 2.7-19.1\% for egg-parr, 2.9$16.8 \%$ for egg-smolt, and $3.8-18.0 \%$ for egg-emigrants. Overwinter survival rates for juvenile spring Chinook within the Chiwawa Basin have ranged from 15.7-100.0\%.

Table 5.18. Productivity (fish/redd) and survival (\%) estimates for different juvenile life stages of spring Chinook in the Chiwawa Basin for brood years 1991-2009; ND = no data. These estimates were derived from data in Table 5.14.

| Brood year | Parr/Redd | Smolts/Redd |  |  |  |  |  |

${ }^{\text {a }}$ These estimates include Chiwawa smolts produced within the Wenatchee Basin. This assumes that $66 \%$ of the subyearling migrants survive to smolt, regardless of the number of subyearling migrants (i.e., no density dependence). Smolt estimates for brood years 1992-1996 were calculated with a mark-recapture model; brood years 1997-present were calculated with a flow model.
${ }^{\mathrm{b}}$ These estimates represent overwinter survival within the Chiwawa Basin. It does not include Chiwawa smolts produced outside the Chiwawa Basin. As noted in footnote $a$, smolts/redd and egg-smolt survival include Chiwawa smolts produced in the Wenatchee Basin.

Seeding level (egg deposition) explained most of the variability in productivity and survival of juvenile spring Chinook in the Chiwawa Basin. That is, for estimates based on "within-Chiwawa-Basin" life stages (e.g., parr and within-Chiwawa-Basin smolts), survival and productivity decreased as seeding levels increased (Figure 5.4). This suggests that density dependence regulates juvenile productivity and survival within the Chiwawa Basin. This form of population regulation is less apparent with total smolts (i.e., Chiwawa smolts produced within the Wenatchee Basin) and total emigrants. However, one would expect the number of emigrants to increases as seeding levels exceed the capacity of the Chiwawa Basin.

Figure 5.4. Relationships between seeding levels (egg deposition) and juvenile life-stage survivals and productivities for Chiwawa spring Chinook, brood years 1991-2008. Total smolts are Chiwawa smolts produced within and outside the Chiwawa Basin (assumes a $66 \%$ survival on subyearling emigrants). Chiwawa smolts are smolts produced only in the Chiwawa Basin.

### 5.5 Spawning Surveys

Surveys for spring Chinook carcasses were conducted during August through September, 2010, in the Chiwawa River (including Rock, Phelps, Big Meadow, and Chikamin creeks), Nason Creek, Icicle Creek, Peshastin Creek (including Ingalls Creek), Upper Wenatchee River (including Chiwaukum Creek), Little Wenatchee River, and White River (including the Napeequa River and Panther Creek).

## Redd Counts

A total of 968 spring Chinook redds were counted in the Wenatchee Basin in 2010 (Table 5.19). This is higher than the average of 576 redds counted during the period 1989-2009 in the Wenatchee Basin. Most spawning occurred in the Chiwawa River (52\% or 502 redds) (Table 5.19; Figure 5.5). Nason Creek contained $19 \%$ (188 redds), White River contained 3\% (33 redds), Little Wenatchee contained $4 \%$ (38 redds), Icicle contained $16 \%$ ( 155 redds), Peshastin Creek contained $1 \%$ ( 5 redds), and the Upper Wenatchee River 5\% ( 47 redds).
Table 5.19. Numbers of spring Chinook redds counted within different streams/watersheds within the Wenatchee Basin, 1989-2010. Redd counts in Peshastin Creek in 2001 and $2002\left({ }^{*}\right)$ were elevated because the U.S. Fish and Wildlife Service planted 487 and 350 spring Chinook adults, respectively, into the stream. These counts were not included in the total or average calculations.

| Sample year | Number of spring Chinook redds |  |  |  |  |  |  |  |

Figure 5.5. Percent of the total number of spring Chinook redds counted in different streams/watersheds within the Wenatchee Basin during August through September, 2010.

## Redd Distribution

Spring Chinook redds were not evenly distributed among reaches within survey streams in 2010 (Table 5.20). Most of the spawning in the Chiwawa Basin occurred in Reaches 1 and 2. Over half of all the spawning in the Chiwawa Basin occurred in the lower two reaches (RM 0.0-19.3; from the mouth to Rock Creek). Relatively few fish spawned in Rock and Chikamin creeks. The spatial distribution of redds in Nason Creek was weighted towards Reach 3, having 33\% of the Nason Creek redds. In the Little Wenatchee River, $92 \%$ of all spawning occurred in Reach 3 (RM 5.2-9.2; Lost Creek to Rainy Creek). On the White River, $85 \%$ occurred in Reach 3 (RM 11.0-12.9; Napeequa River to Grasshopper Meadows). Seventy five percent of all the spawning in the Wenatchee River occurred upstream from the mouth of the Chiwawa River.

Table 5.20. Numbers and proportions of spring Chinook redds counted within different streams/watersheds within the Wenatchee Basin during August through September, 2010.

| Stream/watershed | Reach | Number of redds | Proportion of redds within stream/watershed |

## Spawn Timing

Spring Chinook began spawning during the second week of August in the Chiwawa River, White River, Little Wenatchee, and Nason Creek, and the fourth week in the Upper Wenatchee River (Figure 5.6). Spawning generally peaked the fourth and fifth weeks of August. All spawning was completed by the end of September.

Figure 5.6. Proportion of spring Chinook redds counted during different weeks in different sampling streams within the Wenatchee Basin, August through September 2010.
The temporal distribution of spawning activity in the Chiwawa River in 2010 occurred earlier than the mean 1991-2009 spawning distribution for the Chiwawa (Figure 5.7). The greatest difference in distributions was noted in early August.

## Chiwawa Spring Chinook

Figure 5.7. Comparison of the number of new spring Chinook redds counted during different weeks in the Chiwawa Basin, August through September, 2010, to the overall average.

## Spawning Escapement

Spawning escapement for spring Chinook was calculated as the number of redds times the male-to-female ratio (i.e., fish per redd expansion factor) estimated from broodstock and fish sampled at adult trapping sites. The estimated fish per redd ratio for spring Chinook upstream from Tumwater in 2010 was 2.14 (based on sex ratios estimated at Tumwater Dam). The estimated fish per redd ratio for spring Chinook downstream from Tumwater (Icicle and Peshastin creeks) was 2.72 (derived from broodstock collected at the Leavenworth National Fish Hatchery). Multiplying these ratios by the number of redds counted in the Wenatchee Basin resulted in a total spawning escapement of 2,165 spring Chinook (Table 5.21). The Chiwawa Basin had the highest spawning escapement ( 1,074 Chinook), while Peshastin Creek had the lowest.
Table 5.21. Number of redds, fish per redd ratios, and total spawning escapement for spring Chinook in the Wenatchee Basin, 2010. Spawning escapement was estimated as the product of redds times fish per redd.

| Sampling area | Total number of redds | Fish/redd | Total spawning escapement* |
| :--- | :---: | :---: | :---: |
| Chiwawa | 502 | 2.14 | 1,074 |
| Nason | 188 | 2.14 | 402 |
| Upper Wenatchee River | 47 | 2.14 | 101 |
| Icicle | 155 | 2.72 | 422 |
| Little Wenatchee | 38 | 2.14 | 81 |
| White | 33 | 2.14 | 71 |
| Peshastin | 5 | 2.72 | 14 |
|  | $\mathbf{9 6 8}$ | - | $\mathbf{2 , 1 6 5}$ |

* Spawning escapement estimate is based on total number of redds by stream. If escapement is calculated at the reach scale, then the total escapement may vary from what is shown here because of rounding errors.

The estimated total spawning escapement of 2,197 spring Chinook in 2010 was greater than the overall average of 1,267 spring Chinook (Table 5.22). The escapement in the Chiwawa Basin in 2010 was over twice the escapement in Icicle Creek, the second most abundant stream in the Wenatchee Basin (Table 5.22).
Table 5.22. Spawning escapements for spring Chinook in the Wenatchee Basin for return years 19892010; NA = not available.

${ }^{\text {a }}$ In 2004 the fish/redd expansion estimate of 3.56 was applied to the Chiwawa River only and 3.00 fish/redd for the rest of the upper basin.

### 5.6 Carcass Surveys

Surveys for spring Chinook carcasses were conducted during August through September, 2010, in the Chiwawa River (including Rock, Phelps, Big Meadow, and Chikamin creeks), Nason Creek, Icicle Creek, Peshastin Creek (including Ingalls Creek), Upper Wenatchee River (including Chiwaukum Creek), Little Wenatchee River, and White River (including the Napeequa River and Panther Creek).

## Number sampled

A total of 423 spring Chinook carcasses were sampled during August through September in the Wenatchee Basin (Table 5.23). Most were sampled in the Chiwawa Basin ( $46 \%$ or 193 carcasses) and Nason Creek ( $33 \%$ or 141 carcasses) (Figure 5.8). A total of 39 carcasses were sampled in Icicle Creek, seven in the Little Wenatchee, 11 in the White River, 30 in the upper Wenatchee River, and two in Peshastin Creek.

## Spring Chinook Carcasses

River/Watershed
Figure 5.8. Percent of the total number of spring Chinook carcasses sampled in different streams/watersheds within the Wenatchee Basin during August through September, 2010.

## Carcass Distribution and Origin

Spring Chinook carcasses were not evenly distributed among reaches within survey streams in 2010 (Table 5.24). Most of the carcasses in the Chiwawa Basin occurred in Reaches 1 and 2 (downstream from Rock Creek). In Nason Creek, most carcasses (35\%) were collected in Reach 1 and the fewest (14\%) in Reach 4. Most of the carcasses in the Little Wenatchee River (71\%) were sampled in Reach 3 (Lost Creek to Rainy Creek). On the White River, $100 \%$ occurred in Reach 3 (Napeequa River to Grasshopper Meadows). On the Wenatchee River, 20 carcasses were found upstream from the confluence of the Chiwawa River and ten were found below the confluence.

Table 5.24. Numbers and proportions of carcasses sampled within different streams/watersheds within the Wenatchee Basin during August through September, 2010.

| Stream/watershed | Reach | Number of carcasses | Proportion of redds within stream/watershed |

Of the 423 carcasses sampled in 2010, $30 \%$ were hatchery fish recovered in the Chiwawa River Basin (Table 5.25; these numbers may change after analysis of CWTs). Within the Chiwawa Basin, the spatial distribution of hatchery and wild fish was not equal (Table 5.25). A larger percentage of hatchery fish were found in the lower reaches ( C 1 and C 2 ; Mouth to Rock Creek) than were wild fish. This general trend was also apparent in the pooled data (Figure 5.9).

Table 5.25. Numbers of wild and hatchery spring Chinook carcasses sampled within different reaches in the Chiwawa Basin, 1993-2010. See Table 2.8 for description of survey reaches.

| Survey year | Origin | Survey Reach |  |  |  |  |  |  |  | Total |

## Spring Chinook Carcass Distribution

Figure 5.9. Distribution of wild and hatchery produced carcasses in different reaches in the Chiwawa Basin, 1993-2010; Chik = Chikamin Creek and Rock = Rock Creek. Reach codes are described in Table 2.8.

## Sampling Rate

Overall, $19 \%$ of the estimated total spawning escapement of spring Chinook in the Wenatchee Basin was sampled in 2010 (Table 5.26). Sampling rates among streams/watershed varied from 8 to $34 \%$.

Table 5.26. Number of redds and carcasses, total spawning escapement, and sampling rates for spring Chinook salmon in the Wenatchee Basin, 2010.

| Sampling area | Total number of <br> redds | Total number of <br> carcasses | Total spawning <br> escapement | Sampling rate |

## Length Data

Mean lengths ( $\mathrm{POH}, \mathrm{cm}$ ) of male and female spring Chinook carcasses sampled during surveys in the Wenatchee Basin in 2010 are provided in Table 5.27. The average sizes of males and females sampled in the Wenatchee Basin were 62 and 63 cm , respectively.

Table 5.27. Mean lengths (postorbital-to-hypural length; cm ) and standard deviations (in parentheses) of male and female spring Chinook carcasses sampled in different streams/watersheds in the Wenatchee Basin, 2010.

| Stream/watershed | Mean lengths (cm) |  |
| :--- | :---: | :---: |
|  | Male | Female |
| Chiwawa | $63(9.5)$ | $64(4.2)$ |

### 5.7 Life History Monitoring

Life history characteristics of spring Chinook were assessed by examining carcasses on spawning grounds and fish collected at broodstock collection sites, and by reviewing tagging data and fisheries statistics.

## Migration Timing

There was little difference in migration timing of hatchery and wild spring Chinook past Tumwater Dam (Table 5.28a and b; Figure 5.10). On average, early in the migration, wild Chinook arrived at Tumwater Dam slightly earlier than hatchery fish, but by the end of the migration, both were arriving at about the same time. Most hatchery and wild spring Chinook migrated upstream past Tumwater Dam during June and July (Figure 5.10).

Table 5.28a. The Julian day and date that $10 \%, 50 \%$ (median), and $90 \%$ of the wild and hatchery spring Chinook salmon passed Tumwater Dam, 1998-2010. The average Julian day and date are also provided. Migration timing is based on video sampling at Tumwater. Data for 1998 through 2003 were based on videotapes and broodstock trapping and may not reflect the actual number of hatchery spring Chinook. All spring Chinook were visually examined during trapping from 2004 to present.

| Survey year | Origin | Spring Chinook Migration Time (days) |  |  |  |  |  |  |  | Sample size |

## Spring Chinook Migration Timing

Figure 5.10. Proportion of wild and hatchery spring Chinook observed (using video) passing Tumwater Dam each week during their migration period May through September; data were pooled over survey years 1998-2010.

## Age at Maturity

Most of the wild and hatchery spring Chinook sampled during the period 1994-2010 in the Chiwawa Basin were age-4 fish (total age) (Table 5.29; Figure 5.11). On average, hatchery fish made up a higher percentage of age- 3 and 4 Chinook than did wild fish. In contrast, a higher proportion of age- 5 wild fish returned than did age- 5 hatchery fish. Thus, wild fish tended to return at an older age than hatchery fish.
Table 5.29. Proportions of wild and hatchery spring Chinook of different ages (total age) sampled on spawning grounds in the Chiwawa Basin, 1994-2010.

${ }^{\text {a }}$ These years include carcass and live fish PIT-tag detection data (fish that were sampled both as carcasses and detected as live fish on the spawning grounds were not counted twice). Also origin assignments have been made to fish that were previously identified as fish of unknown origin.

## Spring Chinook Age Structure

Figure 5.11. Proportions of wild and hatchery spring Chinook of different total ages sampled at the Chiwawa Weir and on spawning grounds in the Chiwawa Basin for the combined years 1994-2010.

## Size at Maturity

On average, hatchery and wild spring Chinook of a given age differed slightly in length (Table 5.30). For example, wild age- 5 fish were larger on average than the age- 5 hatchery fish. In contrast, hatchery age- 3 and 4 Chinook were generally larger than age- 3 and 4 wild fish.

Table 5.30. Mean lengths ( POH in $\mathrm{cm} ; \pm 1 \mathrm{SD}$ ) and sample sizes (in parentheses) of different ages (total age) of male and female spring Chinook of wild and hatchery-origin sampled in the Chiwawa Basin, 1994-2010. Brood years 2004-2010 include carcasses and live fish PIT-tag detections. In addition, 2005 and 2006 include fish released at the weir.

## Contribution to Fisheries

Nearly all the harvest on hatchery-origin Chiwawa spring Chinook occurs within the Columbia Basin. Ocean catch records (Pacific Fishery Management Council) indicate that virtually no Upper Columbia spring Chinook are taken in ocean fisheries. Most of the harvest on hatcheryorigin Chiwawa spring Chinook occurs in the Lower Columbia River fisheries, which are managed by the states and tribes pursuant to management plans developed in U.S. v Oregon. The Lower Columbia River fisheries occur during what is referred to in U.S.v Oregon as the winter, spring, and summer seasons, which begin in February and ends July 31 of each year. The Tribal fishery occurs upstream from Bonneville Dam, but primarily in Zone 6, the area between Bonneville and McNary dams; the non-treaty commercial fisheries occur in Zones 1-5, which are downstream from Bonneville Dam. The non-treaty recreational (sport) fishery occurs in the lower mainstem.

The total number of hatchery-origin spring Chinook captured in different fisheries has been relatively low (Table 5.31). The largest harvests occurred on the 1997, 1998, and 2004 brood years.
Table 5.31. Estimated number and percent (in parentheses) of hatchery-origin Chiwawa spring Chinook captured in different fisheries, brood years 1989-2004; $\mathrm{NP}=$ no hatchery program.

${ }^{\text {a }}$ Includes the Wanapum fishery.

## Straying

Stray rates were determined by examining CWTs recovered on spawning grounds within and outside the Wenatchee Basin. Targets for strays based on return year (recovery year) within the Wenatchee Basin should be less than $10 \%$ and targets for strays outside the Wenatchee Basin should be less than $5 \%$. The target for brood year stray rates should be less than $5 \%$.

Rates of hatchery-origin Chiwawa spring Chinook straying into non-target spawning areas within the Wenatchee Basin have been high in some years and exceeded the target of $10 \%$ (Table 5.32). They have strayed into spawning areas on Nason Creek, the White River, the Little Wenatchee River, and the Upper Wenatchee River. On average, stray rates are typically highest in Nason Creek and the Upper Wenatchee River. Stray rates of hatchery-origin Chiwawa spring Chinook should decrease with the change in source water that was implemented in 2006 for the Chiwawa rearing ponds.

Table 5.32. Number (No.) and percent (\%) of the spawning escapement in other non-target spawning streams within the Wenatchee Basin that consisted of hatchery-origin Chiwawa spring Chinook, return years 1992-2009. For example, for return year 2001, $35.3 \%$ of the spring Chinook spawning escapement in Nason Creek consisted of hatchery-origin Chiwawa spring Chinook. Percent strays should be less than 10\%.

Rates of hatchery-origin Chiwawa spring Chinook straying into basins outside the Wenatchee have been low (Table 5.33). Hatchery-origin Chiwawa spring Chinook have strayed into the Methow and Entiat basins. During return years 2002, 2006, 2008, and 2009, their stray rates exceeded the target of 0.05 in the Entiat Basin. Stray rates of Chiwawa spring Chinook should decrease with the change in source water that was implemented in 2006 for the Chiwawa rearing ponds.

Table 5.33. Number and percent of spawning escapements within other non-target basins that consisted of hatchery-origin Chiwawa spring Chinook, return years 1992-2009. For example, for return year 2002, $9.2 \%$ of the spring Chinook spawning escapement in the Entiat Basin consisted of hatchery-origin Chiwawa spring Chinook. Percent strays should be less than $5 \%$. NS $=$ not sampled.

On average, about $36 \%$ of the hatchery returns have strayed into non-target spawning areas, exceeding the target of $5 \%$ (Table 5.34). Depending on brood year, percent strays into non-target spawning areas have ranged from $0-81 \%$. Few ( $<1 \%$ ) have strayed into non-target hatchery programs. Stray rates of hatchery-origin Chiwawa spring Chinook should decrease with the change in source water that was implemented in 2006 for the Chiwawa rearing ponds.
Table 5.34. Number and percent of hatchery-origin Chiwawa spring Chinook that homed to target spawning areas and the target hatchery program, and number and percent that strayed to non-target spawning areas and non-target hatchery programs, by brood years 1989-2004. Percent stays should be less than 5\%.

## Genetics

Genetic studies were conducted to determine the potential impacts of the Chiwawa Supplementation Program on natural-origin spring Chinook in the upper Wenatchee Basin (Blankenship et al. 2007; the entire report is appended as Appendix I). Microsatellite DNA allele frequencies collected from temporally replicated natural and hatchery-origin spring Chinook were used to statistically assign individual fish to specific demes (locations) within the Wenatchee population. In addition, genetic effects of the hatchery program were assessed by examining relationships between census and effective population sizes ( $\mathrm{N}_{\mathrm{e}}$ ) from samples collected before and after supplementation.
Overall, this work showed that although allele frequencies within and between natural and hatchery-origin spring Chinook were significantly different, there was no evidence (i.e., robust signal) that the difference was the result of the hatchery program. Rather, the differences were more likely the result of life history characteristics. However, there was an increasing trend toward homogenization of the allele frequencies of the natural and hatchery-origin fish that comprised the broodstock, even though there was consistent year-to-year variation in allele frequencies among hatchery and natural-origin fish. In addition, there were no robust signals indicating that hatchery-origin hatchery broodstock, hatchery-origin natural spawners, naturalorigin hatchery broodstock, and natural-origin natural spawners were substantially different from each other. Finally, the $\mathrm{N}_{\mathrm{e}}$ estimate of 387 was only slightly larger than the pre-hatchery $\mathrm{N}_{\mathrm{e}}$ (based on demographic data from 1989-1992), which means that the Chiwawa hatchery program has not reduced the $\mathrm{N}_{\mathrm{e}}$ of the Wenatchee spring Chinook population.

Significant differences in allele frequencies were observed within and among major spawning areas in the Upper Wenatchee Basin. However, these differences made up only a very small portion of the overall variation, indicating genetic similarity among the major spawning areas. There was no evidence that the Chiwawa program has changed the genetic structure (allele frequency) of spring Chinook in Nason Creek and the White River, despite the presence of hatchery-origin spawners in both systems.

## Proportion of Natural Influence

Another method for assessing the genetic risk of a supplementation program is to determine the influence of the hatchery and natural environments on the adaptation of the composite population. This is estimated by the proportion of natural-origin fish in the hatchery broodstock ( pNOB ) and the proportion of hatchery-origin fish in the natural spawning escapement ( pHOS ). The ratio $\mathrm{pNOB} /(\mathrm{pHOS}+\mathrm{pNOB})$ is the Proportion of Natural Influence (PNI). The larger the ratio ( PNI ), the greater the strength of selection in the natural environment relative to that of the hatchery environment. In order for the natural environment to dominate selection, PNI should be greater than 0.5 (HSRG/WDFW/NWIFC 2004).

For brood years 1989-1996, the PNI was greater than 0.50, indicating that the natural environment had a greater influence on adaptation of Chiwawa spring Chinook than did the hatchery environment (Table 5.35). For brood years 1997-2009, however, the PNI was generally less than 0.50 , indicating that the hatchery environment had a greater influence on adaptation than did the natural environment.

Table 5.35. Proportionate natural influence (PNI) of the Chiwawa spring Chinook supplementation program for brood years 1989-2009. PNI was calculated as the proportion of naturally produced Chinook in the hatchery broodstock ( pNOB ) divided by the proportion of hatchery Chinook on the spawning grounds (pHOS) plus pNOB. NOS = number of natural-origin Chinook on the spawning grounds; HOS = number of hatchery-origin Chinook on the spawning grounds; NOB = number of natural-origin Chinook collected for broodstock; and HOB = number of hatchery-origin Chinook included in hatchery broodstock.

| Brood year | Spawners |  |  | Broodstock |  |  | PNI |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |

| Average | 251 | 316 | 0.45 | 46 | 71 | 0.48 | 0.52 |

## Natural and Hatchery Replacement Rates

Natural replacement rates (NRR) were calculated as the ratio of natural-origin recruits (NOR) to the parent spawning population (spawning escapement). For brood years 1989-2004, NRR for spring Chinook in the Chiwawa averaged 1.06 (range, 0.00-4.27) if harvested fish were not include in the estimate and 1.15 (range, 0.00-4.73) if harvested fish were included in the estimate (Table 5.36). NRRs for more recent brood years will be calculated as soon as all tag recoveries and sampling rates have been loaded into the database.

Hatchery replacement rates (HRR) are the hatchery adult-to-adult returns and were calculated as the ratio of hatchery-origin recruits (HOR) to the parent broodstock collected. These rates should
be greater than the NRRs and greater than or equal to 5.30 (the calculated target value in Murdoch and Peven 2005). In nearly all years, HRRs were greater than NRRs, regardless if harvest was or was not included (Table 5.36). HRRs exceeded the estimated target value of 5.3 in seven of the 16 years.

Table 5.36. Broodstock collected, spawning escapements, natural and hatchery-origin recruits (NOR and HOR), and natural and hatchery replacement rates (NRR and HRR; with and without harvest) for spring Chinook in the Chiwawa Basin, brood years 1989-2003; NP = no hatchery program.

| Brood year | Broodstock Collected | Spawning Escapement | Harvest not included |  |  |  | Harvest included |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  |  |  | HOR | NOR | HRR | NRR | HOR | NOR | HRR | NRR |
| 1989 | 28 | 713 | 180 | 167 | 6.43 | 0.23 | 204 | 189 | 7.29 | 0.27 |

## Smolt-to-Adult Survivals

Smolt-to-adult survival ratios (SARs) were calculated as the number of hatchery adult recaptures divided by the number of tagged hatchery smolts released. SARs were based on CWT returns. For the available brood years, SARs have ranged from 0.00036 to 0.01562 for hatchery spring Chinook (Table 5.37).

Table 5.37. Smolt-to-adult ratios (SARs) for Chiwawa hatchery spring Chinook, brood years 1989-2004.

| Brood year | Number of tagged smolts <br> released $^{\mathbf{a}}$ | Estimated adult captures $^{\mathbf{b}}$ | SAR |
| :---: | :---: | :---: | :---: |
| 1989 | 42,707 | 204 | 0.00478 |
| 1990 | 52,798 | 19 | 0.00036 |
| 1991 | 61,088 | 36 | 0.00059 |
| 1992 | 82,976 | 31 | 0.00037 |
| 1993 | 221,316 | 284 | 0.00128 |

| Brood year | Number of tagged smolts <br> released |  |  |
| :---: | :---: | :---: | :---: |
| 1994 | 27,135 | Estimated adult captures $^{\mathbf{b}}$ | SAR |
| 1995 |  | 21 | 0.00077 |
| 1996 | 12,767 | No hatchery program |  |
| 1997 | 259,585 | 67 | 0.00525 |
| 1998 | 71,571 | 2,549 | 0.00982 |
| 1999 |  | 1,118 | 0.01562 |
| 2000 | 46,726 | No hatchery program |  |
| 2001 | 374,129 | 375 | 0.00803 |
| 2002 | 145,074 | 1,830 | 0.00489 |
| 2003 | 216,702 | 760 | 0.00524 |
| 2004 | 491,987 | 763 | 0.00352 |
| Average | 150,469 | 2,973 | 0.00604 |

${ }^{\text {a }}$ Includes all tag codes and CWT released fish (CWT + Ad Clip fish and CWT-only fish).
${ }^{\mathrm{b}}$ Includes estimated recoveries (spawning ground, hatcheries, harvest, etc.) and observed recoveries if estimated recoveries were unavailable.

### 5.8 ESA/HCP Compliance

## Broodstock Collection

The collection of 2008 Brood Chiwawa River spring Chinook broodstock was consistent with the 2008 Upper Columbia River salmon and steelhead broodstock objectives and site-based broodstock collection protocols. Specifically, broodstock collection targeted hatchery-origin fish at Tumwater Dam and the Chiwawa Weir, while only natural-origin spring Chinook were collected at the Chiwawa Weir. In-season adjustments were made to the number of hatchery and natural-origin spring Chinook collected for bloodstock and were based on in-season escapement monitoring at Tumwater Dam and estimated Chiwawa run-escapement.
Broodstock collection at Tumwater Dam began 10 June 2008, concluded on 29 July 2008, and targeted hatchery-origin, coded-wire tagged spring Chinook. Collection was implemented concurrent with trapping, sampling, and tagging associated with the spring Chinook reproductive success study (BPA project No. 2003-039-00). Trapping at the Chiwawa Weir began on 8 July 2008 and concluded on 26 August 2008. Broodstock collection targeted natural-origin spring Chinook and hatchery-origin spring Chinook as needed to attain a minimum 33\% natural-origin broodstock and a maximum $33 \%$ extraction of the estimated natural-origin return to the Chiwawa River.
The BY 2008 brood collection retained a total of 329 spring Chinook, including 88 natural-origin fish, representing a $27 \%$ natural-origin broodstock. The brood collection failed to meet the targeted $33 \%$ natural-origin composition primarily because of false negative wire detection at Chiwawa weir that underestimated the number of hatchery-origin Chinook retained.

Both passive (low abundance periods) and active (high abundance periods) trapping were used to collect spring Chinook at Tumwater Dam. During passive trapping, the trap was checked and fish were processed several times per day. At the Chiwawa Weir, the trap was operated passively, checked several times per day, and fish were processed once daily. Trapping at the Chiwawa Weir generally followed a four-up and three-down schedule, and operated only as needed to meet weekly collection objectives consistent with the 2008 collection protocol or as adjusted based on in-season run escapement monitoring and ESA Section 10 Permit 1196 requirements. All spring Chinook, steelhead, and bull trout that were captured were anesthetized with tricaine methanesulfonate (MS-222) and subject to water-to-water transfers during handling. All fish were allowed to fully recover before release.
The estimated escapement of 2008 spring Chinook past Tumwater Dam totaled 5,514 adult and jack spring Chinook (Murdoch et al. 2008). Based on 2008 spawning ground data (redd and carcass surveys), an estimated 208 natural-origin spring Chinook spawned in the Chiwawa River Basin (Table 5.34). Assuming the pre-spawn survival of Chiwawa River natural-origin spring Chinook was similar to the at-large population upstream from Tumwater Dam (73\%), combined with the 88 natural-origin Chinook extracted for broodstock, the natural-origin escapement to the Chiwawa Basin totaled 373 spring Chinook (i.e., $(208 / 0.73)+88=373)$. The 2008 broodstock retention of 329 spring Chinook ( 88 natural-origin and 241 hatchery-origin) represents $6.2 \%$ of the estimated 2008 Chiwawa spring Chinook escapement ( $24 \%$ of the wild Chiwawa escapement) to Tumwater Dam and $6.0 \%$ of the run escapement of spring Chinook upstream from Tumwater Dam. The estimated broodstock extraction rate of natural-origin Chiwawa spring Chinook and overall extraction of spring Chinook upstream from Tumwater Dam comply with provisions of ESA Permit 1196.

No additional spring Chinook were handled and released as a function of maintaining, at minimum, $33 \%$ natural-origin spring Chinook in the broodstock. About 400 bull trout were captured and released. To minimize fallback or impingement on the weir, all spring Chinook and bull trout were released unharmed about 10 km upstream from the weir.

## Hatchery Rearing and Release

The rearing and release of 2008 Chiwawa spring Chinook was completed without incident. No mortality events occurred that exceeded $10 \%$ of the population. Fish were acclimated on Wenatchee River water and to the extent possible on Chiwawa River water (see Section 5.2).

The release of 2008 brood Chiwawa spring Chinook smolts totaled 609,789 spring Chinook, representing $90.7 \%$ of program objectives and complied with ESA Section 10 Permit 1196 production level of 672,000 smolts.

## Hatchery Effluent Monitoring

Per ESA Permits 1196, 1347, and 1395, permit holders shall monitor and report hatchery effluents in compliance with applicable National Pollution Discharge Elimination Systems (NPDES) (EPA 1999) permit limitations. There were no NPDES violations reported at Chelan PUD Hatchery facilities during the period 1 January 2010 through 31 December 2010. NPDES monitoring and reporting for Chelan PUD Hatchery Programs during 2010 are provided in Appendix E.

## Smolt and Emigrant Trapping

Per ESA Section 10 Permit No. 1196, the permit holders are authorized a direct take of $20 \%$ of the emigrating spring Chinook population during juvenile emigration monitoring and a lethal take not to exceed $2 \%$ of the fish captured (NMFS 2003). Based on the estimated wild spring Chinook population (smolt trap expansion) and hatchery juvenile spring Chinook population estimate (hatchery release data) for the Wenatchee Basin, the reported spring Chinook encounters during 2010 emigration monitoring complied with take provisions in the Section 10 permit. Spring Chinook encounter and mortality rates for each trap site (including PIT tag mortalities) are detailed in Table 5.38. Additionally, juvenile fish captured at the trap locations were handled consistent with provisions in ESA Section 10 Permit 1196, Section B.
Table 5.38. Estimated take of Upper Columbia River spring Chinook resulting from juvenile emigration monitoring in the Wenatchee Basin, 2010.

| Trap location | Population estimate |  |  | Number trapped |  |  | Total | Take allowed under Permit |

${ }^{\mathrm{e}}$ Expanded total Wenatchee Basin natural-origin spring Chinook smolt estimates based on the estimated Chiwawa smolt production and proportion of total redds in the Chiwawa Basin.
${ }^{\mathrm{f}}$ Insufficient numbers of natural-origin spring Chinook were encountered to derive a population estimate

## Spawning Surveys

Spring Chinook spawning ground surveys were conducted in the Wenatchee Basin during 2010, as authorized by ESA Section 10 Permit 1196. Because of the difficulty of quantifying the level of take associated with spawning ground surveys, the Permit does not specify a take level associated with these activities, even though it does authorize implementation of spawning ground surveys. Therefore, no take levels are reported. However, to minimize potential impacts to established redds, wading was restricted to the extent practical, and extreme caution was used to avoid established redds when wading was required.

## Spring Chinook Reproductive Success Study

ESA Section 10 Permit 1196 specifically provides authorization to capture, anesthetize, biologically sample, PIT tag, and release adult spring Chinook at Tumwater Dam for reproductive success studies and general program monitoring. During 2008 through 2009, all spring Chinook passing Tumwater Dam were enumerated, anesthetize, biologically sampled, PIT tagged, and released (not including hatchery-origin Chinook retained for broodstock) as a component of the reproductive success study (BPA Project No. 2003-039-00). Please refer to Murdoch et al. (2008) and Murdoch et al. (2009) for complete details on the methods and results of the spring Chinook reproductive success study for 2008 and 2009.

## SECTION 6: WENATCHEE SUMMER CHINOOK

### 6.1 Broodstock Sampling

This section focuses on results from sampling 2008-2009 Wenatchee summer Chinook broodstock, which were collected at Dryden and Tumwater dams. Complete information is not currently available for the 2010 brood (this information will be provided in the 2011 annual report).

## Origin of Broodstock

Both the 2008 and 2009 broodstock consisted primarily of natural-origin (adipose fin present) summer Chinook (Table 6.1). In order to meet production goals, hatchery-origin adults were collected in concert with natural-origin fish. About $2 \%$ of the 2009 broodstock was comprised of hatchery-origin fish (hatchery-origin was determined by examination of scales and/or CWTs).

Table 6.1. Numbers of wild and hatchery summer Chinook collected for broodstock, numbers that died before spawning, and numbers of Chinook spawned in the Wenatchee Basin, 1989-2009. Unknown origin fish (i.e., undetermined by scale analysis, no CWT or fin clips, and no additional hatchery marks) were considered naturally produced. Mortality includes fish that died of natural causes typically near the end of spawning and were not needed for the program and surplus fish killed at spawning.

| Brood year | Wild summer Chinook |  |  |  |  | Hatchery summer Chinook |  |  |  |  | Total number spawned |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |

## Age/Length Data

Ages of summer Chinook broodstock were determined from analysis of scales and/or CWTs. Broodstock collected from the 2008 return consisted primarily of age-4 natural-origin Chinook ( $65 \%$ ). Age-3, 5, and 6 natural-origin fish collectively made up $34 \%$ of the broodstock, while age-2, fish made up about $1 \%$ (Table 6.2). Of the 72 hatchery Chinook included in the broodstock, $69 \%$ were age- 5 fish with age-4 and 6 comprising $13 \%$ and $15 \%$, respectively. About 3\% of the hatchery broodstock were age- 3 fish.
Broodstock collected from the 2009 return consisted primarily of age-4 and age-5 natural-origin Chinook (93\%). Age-2 and age-3 natural-origin fish collectively made up 7\% of the broodstock. No age-6 fish were included in the broodstock (Table 6.2). Of the hatchery Chinook included in the broodstock, $53 \%$ were age- 5 fish, with age- 3 and 4 comprising $13 \%$ and $34 \%$, respectively. About 3\% of the hatchery broodstock were age- 3 fish.

Table 6.2. Percent of hatchery and wild Wenatchee summer Chinook of different ages (total age) collected from broodstock in the Wenatchee Basin, 1991-2009.

Mean lengths of natural-origin summer Chinook of a given age differed little between return years 2008 and 2009 (Table 6.3). Mean lengths of age-2 and 5 Chinook differed between years by about 2 cm and 3 cm , respectively. The few hatchery fish that were included in broodstock were about 3-9 cm smaller than their natural counterparts in the 2009 brood (Table 6.3).
Table 6.3. Mean fork length ( cm ) at age (total age) of hatchery and wild Wenatchee summer Chinook collected from broodstock in the Wenatchee Basin, 1991-2009; $\mathrm{N}=$ sample size and $\mathrm{SD}=1$ standard deviation.

## Sex Ratios

Male summer Chinook in the 2008 broodstock made up about $50 \%$ of the adults collected, resulting in an overall male to female ratio of 1.01:1.00 (Table 6.4.). In 2009, males made up about $50 \%$ of the adults collected, resulting in an overall male to female ratio of 1.02:1.00 (Table 6.4). The ratios in 2009 were nearly equal to the $1: 1$ ratio goal in the broodstock protocol.

Table 6.4. Numbers of male and female wild and hatchery summer Chinook collected for broodstock in the Wenatchee Basin, 1989-2009. Ratios of males to females are also provided.

| Return year | Number of wild summer Chinook |  |  | Number of hatchery summer Chinook |  |  | Total M/F <br> ratio |

Fecundity
Fecundities for the 2008 and 2009 returns of summer Chinook averaged 5,108 and 5,291 eggs per female, respectively (Table 6.5). These values are close to the overall average of 5,186 eggs per female. Mean observed fecundities for the 2008 and 2009 returns were above the expected fecundity of 5,000 eggs per female assumed in the broodstock protocol.
Table 6.5. Mean fecundity of wild, hatchery, and all female summer Chinook collected for broodstock in the Wenatchee Basin, 1989-2008; NA = not available.

### 6.2 Hatchery Rearing

## Rearing History

## Number of eggs taken

Based on the unfertilized egg-to-release survival standard of $81 \%$, a total of $1,066,667$ eggs are required to meet the program release goal of 864,000 smolts. Between 1989 and 2009, the egg take goal was reached in seven of those years (Table 6.6).

Table 6.6. Numbers of eggs taken from Wenatchee summer Chinook broodstock, 1989-2009.

| Return year | Number of eggs taken |
| :---: | :---: |
| 1989 | 829,012 |
| 1990 | 163,109 |
| 1991 | 247,000 |
| 1992 | 827,911 |
| 1993 | $1,133,852$ |
| 1994 | 999,364 |
| 1995 | 949,531 |
| 1996 | 756,000 |
| 1997 | 554,617 |
| 1998 | 854,997 |
| 1999 | $1,182,130$ |
| 2000 | $1,113,159$ |
| 2001 | 733,882 |
| 2002 | $1,049,255$ |

| 2003 | 901,095 |
| 2004 | $1,311,051$ |
| 2005 | 883,669 |
| 2006 | $1,190,757$ |
| 2007 | 655,201 |
| 2008 | $1,145,330$ |
| 2009 | $1,217,028$ |
| Average | $\mathbf{8 9 0 , 3 7 9}$ |

## Number of acclimation days

The 2008 brood Wenatchee summer Chinook were transferred to Dryden Pond between 9-22 March 2009. These fish received 38-51 days of acclimation on Wenatchee River water before being released on 28 April 2009 (Table 6.7). In recent years, a small proportion of the brood (high ELISA fish) has been reared separately and received no acclimation (i.e., these fish were released directly into the Wenatchee River). These data are not shown in Table 6.7. No such release occurred in 2010.

Table 6.7. Number of days Wenatchee summer Chinook were acclimated at Dryden Pond, brood years 1989-2008. Numbers in parenthesis represents the number of days fish reared at Chiwawa Ponds.

| Brood year | Release year | Transfer date | Release date | Number of days |
| :---: | :---: | :---: | :---: | :---: |
| 1989 | 1991 | 2-Mar | 7-May | 66 |
| 1990 | 1992 | 19-Feb | 2-May | 73 |
| 1991 | 1993 | 10-Mar | 8-May | 59 |
| 1992 | 1994 | 1-Mar | 6-May | 66 |
| 1993 | 1995 | 3-Mar | 1-May | 59 |
| 1994 | 1996 | 2-Oct | 6-May | 217 (154) |
|  |  | 5-Mar | 6-May | 62 |
| 1995 | 1997 | 16-Oct | 8-May | 205 (139) |
|  |  | 27-Feb | 8-May | 70 |
| 1996 | 1998 | 6-Oct | 28-Apr | 204 (142) |

## Release Information

## Numbers released

The 2008 Wenatchee summer Chinook program achieved $103 \%$ of the 864,000 target goal with about 888,811 fish being released (Table 6.8). The slight overage was likely related to above average fecundities while maintaining or exceeding in-hatchery survival goals for the program.

Table 6.8. Numbers of Wenatchee summer Chinook smolts released from the hatchery, 1989-2008. The release target for Wenatchee summer Chinook is 864,000 smolts.

${ }^{\text {a }}$ Represents high Elisa group planted directly in the Wenatchee River at Leavenworth Boat Launch.

## Numbers tagged

The 2008 brood Wenatchee summer Chinook were $96.7 \%$ CWT and adipose fin-clipped (Table 6.8).

In 2010, a total of about 30,300 summer Chinook (brood year 2009) were PIT tagged at Eastbank Fish Hatchery during 7-9, 14-16, and 21-23 September 2010. Fish were tagged in three groups of about 10,100 per group. One group of PIT-tagged Chinook was placed in standard raceway \#13 (Control Group), another group was placed in re-use Circular Pond R-1, and the last group was placed in re-use Circular Pond R-2. Fish were not fed during tagging or for two days before and after tagging. Chinook from the Control Group averaged 84 mm in length and 6.3 g at time of tagging. Fish in R-1 averaged 85 mm in length and 6.4 g , while those in R-2 averaged 90 mm in length and 7.6 g . As of the end of January 2011, a total of 71 tagged Chinook have died ( 14 from the Control Group, 28 from R-1, and 29 from R-2). Three fish have shed their tags, all from the Control Group.
Table 6.9 summarizes the number of hatchery summer Chinook that have been PIT-tagged and released into the Wenatchee River.

Table 6.9. Summary of PIT-tagging activities for Wenatchee hatchery summer Chinook, brood yearS 2008-2009.

| Brood year | Release year | Number of fish <br> tagged | Number of <br> tagged fish that <br> died | Number of tags <br> shed | Number of <br> tagged fish <br> released |

## Fish size and condition at release

About 888,811 summer Chinook from the 2008 brood were released from Dryden Pond using an unmonitored volitional method (i.e., volitional without PIT-tag detection equipment in place) on 28 April 2010. Size at release was $94.3 \%$ and $114.5 \%$ of the target fork length and weight goals, respectively. This brood year exceeded the target CV for length by $44.4 \%$ (Table 6.10 ). Since the program began, Wenatchee summer Chinook have not met the target length and CV values. The target weight (fish/pound or FPP) of juvenile fish has been met occasionally.

Table 6.10. Mean lengths (FL, mm), weight ( g and fish/pound), and coefficient of variation (CV) of Wenatchee summer Chinook smolts released from the hatchery, brood years 1989-2008; NA = not available. Size targets are provided in the last row of the table.

| Brood year | Release year | Fork length (cm) |  | Mean weight |  |
| :---: | :---: | :---: | :---: | :---: | :---: |

## Survival Estimates

Overall survival of the 2008 brood Wenatchee summer Chinook from green (unfertilized) egg to release was slightly below the standard set for the program in part because of not meeting standards in ponding-to-release and transport-to-release survivals (Table 6.11).

Table 6.11. Hatchery life-stage survival rates (\%) for Wenatchee summer Chinook, brood years 19892008. Survival standards or targets are provided in the last row of the table.

### 6.3 Disease Monitoring

Rearing of the 2008 brood Wenatchee summer Chinook was similar to previous years with fish being held on well water before being transferred to Dryden Pond for final acclimation in March 2010. Fish were transferred to Dryden pond from 9 to 22 March. Increased mortality caused by external fungus began to occur during the acclimation period at Dryden pond at which time a formalin treatment was initiated in an attempt to prevent the fungus from proliferating.
Results of the 2010 adult broodstock bacterial kidney disease (BKD) monitoring indicated that most females (99\%) had ELISA values less than 0.199. About 99.5\% of females had ELISA values less than 0.120 , which would require about $0.05 \%$ of the progeny to be reared at densities not to exceed 0.06 fish per pound (Table 6.12).
Table 6.12. Proportion of bacterial kidney disease (BKD) titer groups for the Wenatchee summer Chinook broodstock, brood years 1997-2010. Also included are the proportions to be reared at either 0.125 fish per pound or 0.060 fish per pound.

### 6.4 Natural Juvenile Productivity

During 2010, juvenile summer Chinook were sampled at the Lower Wenatchee Trap located at the West Monitor Bridge.

## Emigrant Estimates

The Lower Wenatchee Trap operated nightly between 4 February and 20 July 2010. During that time period, trap 1 and trap 2 were inoperable for 19 and 68 days, respectively, because of high river flows, debris, snow/ice, or mechanical failure. During the six-month sampling period, a total of 50,685 wild subyearling Chinook were captured at the Lower Wenatchee Trap. Based on capture efficiencies estimated from the flow model, the total number of wild subyearling Chinook that emigrated past the Lower Wenatchee Trap was $6,695,977( \pm 2,435,120)$. Most of these fish emigrated during May (Figure 6.1). Monthly captures and mortalities of all fish collected at the Lower Wenatchee Trap are reported in Appendix B.

Figure 6.1. Numbers of wild subyearling Chinook captured at the Lower Wenatchee Trap during February to August, 2010.

### 6.5 Spawning Surveys

Surveys for Wenatchee summer Chinook redds were conducted from late September to midNovember, 2010, in the Wenatchee River and Icicle Creek. Both peak counts and total counts (based on expansion factors; Murdoch and Peven 2005) were conducted in the river (see Appendix G for more details).

## Redd Counts

A peak count of 2,564 summer Chinook redds was estimated in 2010 based on ground surveys conducted in the Wenatchee River and Icicle Creek (Table 6.13). A total redd count of 3,261 redds was estimated in 2010 based on expanded peak counts and 3,730 based on the naïve expansion method in the Wenatchee Basin (Table 6.13).

Table 6.13. Peak and total numbers of redds counted in the Wenatchee River, 1989-2010; NA = not available. Total counts are based on two different methods: expanded peak counts and naïve expansion methods (see Appendix G for more information).

| Survey year | Peak redd count | Total redd count |  |
| :---: | :---: | :---: | :---: |
|  |  | Peak expansion | Naïve expansion |
| 1989 | 3,331 | 4,215 | NA |
| 1990 | 2,479 | 3,103 | NA |
| 1991 | 2,180 | 2,748 | NA |

| $2010^{*}$ | 2,564 | 3,261 | 3,730 |
| Average | 2,810 | 3,493 | 3,109 |

* Peak and total counts include 68, 13, 23, 21, and 11 redds counted in Icicle Creek in 2006-2010, respectively.

## Redd Distribution

Summer Chinook redds were not evenly distributed among reaches within the Wenatchee Basin in 2010 (Table 6.14; Figure 6.2). Most of the spawning occurred upstream from the Leavenworth Bridge in Reaches 6, 9, and 10. The highest density of redds occurred in Reach 6 near the confluence of the Icicle River.

Table 6.14. Peak and total numbers of summer Chinook redds counted in different reaches in the Wenatchee Basin during September through mid-November, 2010. Reach codes are described in Table 2.10 .

| Survey reach | Peak redd count | Total redd count |  |
| :---: | :---: | :---: | :---: |
|  |  | Peak expansion | Naïve expansion |
| Wenatchee 1 | 12 | 17 | 18 |
| Wenatchee 2 | 129 | 184 | 111 |

## Wenatchee Summer Chinook Redds

Figure 6.2. Percent of the total number (based on peak expansion) of summer Chinook redds counted in different reaches in the Wenatchee Basin during September through mid-November, 2010. Reach codes are described in Table 2.10.

## Spawn Timing

In 2010, spawning in the Wenatchee River began during the first week of October, peaked the third week of October, and ended in early November (Figure 6.3).

Figure 6.3. Number of new summer Chinook redds counted during different weeks in the Wenatchee River, September through mid-November 2010 (based on mapping counts).

## Spawning Escapement

Spawning escapement for Wenatchee summer Chinook was calculated as the total number of redds (expanded peak counts) times the fish per redd ratio estimated from broodstock and fish sampled at adult trapping sites. The estimated fish per redd ratio for summer Chinook in 2010 was 2.29 . Multiplying this ratio by the number of redds counted in the Wenatchee Basin resulted in a total spawning escapement of 7,468 summer Chinook (Table 6.15).
Table 6.15. Spawning escapements for summer Chinook in the Wenatchee Basin, return years 19892010. Number of redds is based on expanded peak redd counts.

| Return year | Fish/Redd | Redds | Total spawning escapement |
| :---: | :---: | :---: | :---: |
| 1989 | 3.40 | 4,215 | 14,331 |

### 6.6 Carcass Surveys

Surveys for Wenatchee summer Chinook carcasses were conducted during late September to mid-November, 2010, in the Wenatchee River and Icicle Creek.

## Number sampled

A total of 1,509 summer Chinook carcasses were sampled during October through midNovember in the Wenatchee Basin in 2010 (Table 6.16).

Table 6.16. Numbers of summer Chinook carcasses sampled within each survey reach in the Wenatchee Basin, 1993-2010. Reach codes are described in Table 2.10.

| Survey year | Number of summer Chinook carcasses |  |  |  |  |  |  |  |  |  |  |  |

## Carcass Distribution and Origin

Summer Chinook carcasses were not evenly distributed among reaches within the Wenatchee Basin in 2010 (Table 6.15; Figure 6.4). Most of the carcasses in the Wenatchee Basin were found upstream from the Leavenworth Bridge. The highest percentage of carcasses (36\%) was sampled in Reach 6 near the confluence of the Icicle River.

## Wenatchee Summer Chinook Carcasses

Figure 6.4. Percent of summer Chinook carcasses sampled within different reaches in the Wenatchee Basin during September through mid-November, 2010. Reach codes are described in Table 2.10.

Numbers of wild and hatchery-origin summer Chinook carcasses sampled in 2010 will be available after analysis of CWTs and scales. Based on the available data (1993-2009), most fish, regardless of origin, were found in Reach 6 (Leavenworth Bridge to Icicle Road Bridge) (Table 6.17). However, a larger percentage of hatchery fish were found in that reach than were wild fish (Figure 6.5). In contrast, a larger percentage of wild fish were found in reaches upstream from the Icicle Road Bridge.

Table 6.17. Numbers of wild and hatchery summer Chinook carcasses sampled within different reaches in the Wenatchee Basin, 1993-2009.

| Survey year | Origin | Survey reach |  |  |  |  |  |  |  |  |  |  | Total |

Figure 6.5. Distribution of wild and hatchery produced carcasses in different reaches in the Wenatchee Basin, 1993-2009. Reach codes are described in Table 2.10.

## Sampling Rate

If escapement is based on total numbers of redds (based on peak expansion), then about $20 \%$ of the total spawning escapement of summer Chinook in the Wenatchee Basin was sampled in 2010 (Table 6.18). Sampling rates among survey reaches varied from 7 to $60 \%$.

Table 6.18. Number of redds and carcasses, total spawning escapement, and sampling rates for summer Chinook in the Wenatchee Basin, 2010.

| Sampling reach | Total number of <br> redds | Total number of <br> carcasses | Total spawning <br> escapement | Sampling rate |
| :---: | :---: | :---: | :---: | :---: |
| Wenatchee 1 | 17 | 3 | 39 | 0.08 |
| Wenatchee 2 | 184 | 31 | 421 | 0.07 |
| Wenatchee 3 | 231 | 98 | 529 | 0.19 |
| Wenatchee 4 | 77 | 57 | 176 | 0.32 |

| Wenatchee 7 | 268 | 136 | 231 | 0.22 |
| Wenatchee 8 | 101 | 49 | 989 | 0.21 |
| Wenatchee 9 | 432 | 124 | 914 | 0.13 |
| Wenatchee 10 | 399 | 193 | 25 | 0.21 |
| Icicle Creek | 11 | $\mathbf{1 5}$ | $\mathbf{7 , 5 0 9}$ | 0.60 |
| Total | $\mathbf{3 , 2 6 1}$ |  | 0.20 |  |

## Length Data

Mean lengths ( $\mathrm{POH}, \mathrm{cm}$ ) of male and female summer Chinook carcasses sampled during surveys in the Wenatchee Basin in 2010 are provided in Table 6.19. The average size of males and females sampled in the Wenatchee basin were 68 cm and 72 cm , respectively.
Table 6.19. Mean lengths (postorbital-to-hypural length; cm ) and standard deviations (in parentheses) of male and female summer Chinook carcasses sampled in different streams/watersheds in the Wenatchee Basin, 2010.

| Stream/watershed | Mean length (cm) |  |
| :---: | :---: | :---: |
|  | Male | Female |
| Wenatchee 1 | $75.0(17.0)$ | NA |
| Wenatchee 2 | $66.8(9.1)$ | $72.3(4.4)$ |
| Wenatchee 3 | $65.5(10.3)$ | $68.3(6.9)$ |
| Wenatchee 4 | $65.5(12.9)$ | $75.0(5.9)$ |
| Wenatchee 5 | $62.3(10.0)$ | $70.5(5.0)$ |
| Wenatchee 6 | $65.8(9.3)$ | $68.9(6.4)$ |
| Wenatchee 7 | $67.8(9.7)$ | $69.9(5.0)$ |
| Wenatchee 8 | $65.0(10.1)$ | $69.5(5.5)$ |
| Wenatchee 9 | $66.8(9.6)$ | $69.7(4.5)$ |
| Wenatchee 10 | $67.1(7.2)$ | $69.5(4.4)$ |
| Icicle Creek | $68.0(7.8)$ | $71.5(4.5)$ |
| Total | $\mathbf{6 8 . 4}(\mathbf{1 1 . 7})$ | $\mathbf{7 1 . 8} \mathbf{( 5 . 4 )}$ |

### 6.7 Life History Monitoring

Life history characteristics of Wenatchee summer Chinook were assessed by examining carcasses on spawning grounds and fish collected or examined at broodstock collection sites, and by reviewing tagging data and fisheries statistics.

## Migration Timing

Migration timing of hatchery and wild Wenatchee summer Chinook was determined from broodstock data and stock assessment data collected at Dryden Dam. Sampling at Dryden Dam occurs from early July through mid-October. During that period, hatchery summer Chinook arrived about 1-2 weeks before wild Chinook in 2010 (Table 6.20). This pattern was different in previous years when wild fish arrived about 1-2 weeks earlier than hatchery fish. This latter pattern was also observed when data were pooled for the 2007-2010 survey period.
Table 6.20. The week that $10 \%, 50 \%$ (median), and $90 \%$ of the wild and hatchery summer Chinook salmon passed Dryden Dam, 2007-2010. The average week is also provided. Migration timing is based on collection of summer Chinook broodstock at Dryden Dam.

| Survey year | Origin | Wenatchee Summer Chinook Migration Time (week) |  |  | Sample size |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |

## Age at Maturity

Most of the wild and hatchery summer Chinook sampled during the period 1993-2009 in the Wenatchee Basin were age-5 fish (total age) (Table 6.21; Figure 6.6). A higher percentage of age-4 wild Chinook returned to the basin than did age- 4 hatchery Chinook. In contrast, a higher proportion of age- 6 hatchery fish returned than did age- 6 wild fish. Thus, a higher percentage of hatchery fish returned at an older age than did wild fish.
Table 6.21. Proportions of wild and hatchery summer Chinook of different ages (total age) sampled on spawning grounds in the Wenatchee Basin, 1993-2009.

| Sample year | Origin | Total age |  |  |  |  |  |  |

Wenatchee Summer Chinook

Figure 6.6. Proportions of wild and hatchery summer Chinook of different total ages sampled at broodstock collection sites and on spawning grounds in the Wenatchee Basin for the combined years 1993-2009.

## Size at Maturity

On average, hatchery summer Chinook were about 4 cm smaller than wild summer Chinook sampled in the Wenatchee Basin (Table 6.22). This is interesting given that a slightly higher percentage of hatchery fish returned as age-5 and 6 fish than did wild fish. Future analyses will compare sizes of hatchery and wild fish of the same age groups and gender.

Table 6.22. Mean lengths ( $\mathrm{POH} ; \mathrm{cm}$ ) and variability statistics for wild and hatchery summer Chinook sampled in the Wenatchee Basin, 1993-2009; SD = 1 standard deviation.

## Contribution to Fisheries

Most of the harvest on hatchery-origin Wenatchee summer Chinook occurred in the ocean (Table 6.23). Ocean harvest has made up $50 \%$ to $100 \%$ of all hatchery Wenatchee summer Chinook harvested. Total harvest on early brood years (1990-1996) was lower than for later brood years (1997-2004).
Table 6.23. Estimated number and percent (in parentheses) of hatchery-origin Wenatchee summer Chinook captured in different fisheries, brood years 1989-2004.

| Brood year | Ocean fisheries | Columbia River Fisheries |  |  | Total |
| :---: | :---: | :---: | :---: | :---: | :---: |

## Straying

Stray rates were determined by examining CWTs recovered on spawning grounds within and outside the Wenatchee Basin. Targets for strays based on return year (recovery year) and brood year should be less than $5 \%$.

On average, rates of hatchery-origin Wenatchee summer Chinook straying into basins outside the Wenatchee have been low (Table 6.24). Although hatchery-origin Wenatchee summer Chinook have strayed into other spawning areas, straying has generally been less than $5 \%$. In four different years, Wenatchee strays have made up more than $5 \%$ of the spawning escapement in the Entiat Basin and Chelan tailrace. Wenatchee strays have made up more than $5 \%$ of spawning escapement in the Methow Basin in five different years.

Table 6.24. Number and percent of spawning escapements within other non-target basins that consisted of hatchery-origin Wenatchee summer Chinook, return years 1994-2007. For example, for return year 2000, $3 \%$ of the summer Chinook escapement in the Methow Basin consisted of hatchery-origin Wenatchee summer Chinook. Percent strays should be less than 5\%.

| Return year | Methow |  | Okanogan |  | Chelan |  | Entiat |  | Hanford Reach |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  | Number | \% | Number | \% | Number | \% | Number | \% | Number | \% |

| 1996 | 0 | 0.0 | 0 | 0.0 | - | - | - | - | - | - |
| 1997 | 0 | 0.0 | 0 | 0.0 | - | - | - | - | - | - |
| 1998 | 25 | 3.7 | 0 | 0.0 | 0 | 0.0 | 0 | 0.0 | 0 | 0.0 |
| 1999 | 20 | 2.0 | 3 | 0.1 | 0 | 0.0 | 0 | 0.0 | 13 | 0.1 |
| 2000 | 36 | 3.0 | 13 | 0.4 | 0 | 0.0 | 0 | 0.0 | 0 | 0.0 |
| 2001 | 163 | 5.9 | 57 | 0.5 | 30 | 3.0 | 0 | 0.0 | 0 | 0.0 |
| 2002 | 153 | 3.3 | 53 | 0.4 | 40 | 6.9 | 74 | 14.8 | 0 | 0.0 |
| 2003 | 80 | 2.0 | 24 | 0.7 | 44 | 10.5 | 132 | 19.1 | 26 | 0.0 |
| 2004 | 113 | 5.2 | 42 | 0.6 | 30 | 7.1 | 0 | 0.0 | 0 | 0.0 |
| 2005 | 245 | 9.6 | 67 | 0.8 | 51 | 11.5 | 49 | 13.4 | 0 | 0.0 |
| 2006 | 170 | 6.2 | 12 | 0.1 | 12 | 2.9 | 18 | 3.1 | 0 | 0.0 |
| 2007 | 127 | 9.3 | 5 | 0.1 | 9 | 4.8 | 18 | 7.3 | 20 | 0.1 |
| Total | 1,132 | 4.2 | 351 | 0.5 | 216 | 5.0 | 291 | 8.3 | 59 | 0.0 |

On average, about $11 \%$ of the hatchery-origin Wenatchee summer Chinook returns have strayed into non-target spawning areas, exceeding the target of $5 \%$ (Table 6.25). Depending on brood year, percent strays into non-target spawning areas have ranged from $0-19 \%$. In addition, on average, about $5.5 \%$ have strayed into non-target hatchery programs, but straying into non-target programs has declined over time.

Table 6.25. Number and percent of hatchery-origin Wenatchee summer Chinook that homed to target spawning areas and the target hatchery program, and number and percent that strayed to non-target spawning areas and non-target hatchery programs, by brood years 1989-2004. Percent stays should be less than 5\%.

| Brood year | Homing |  |  |  | Straying |  |  |  |

## Genetics

Genetic studies were conducted to investigate relationships among temporally replicated collections of summer Chinook from the Wenatchee River, Methow River, and Okanogan River in the upper Columbia River basin (Kassler et al. 2100; the entire report is appended as Appendix J). Samples from the Eastbank Hatchery - Wenatchee stock, Eastbank Hatchery Methow/Okanogan (MEOK) stock, and Wells Hatchery were also included in the analysis. Samples of natural and hatchery-origin summer Chinook were analyzed and compared to determine if the supplementation program has affected the genetic structure of these populations. The study also calculated the effective number of breeders for collection locations of natural and hatchery-origin summer Chinook from 1993 and 2008.

In general, population differentiation was not observed among the temporally replicated collection locations. A single collection from the Okanogan River (1993) was the only collection showing statistically significant differences. The effective number of breeders was not statistically different from the early collection in 1993 in comparison to the late collection in 2008. Overall, these analyses revealed a lack of differentiation among the temporal replicates
from the same locations and among the collection from different locations, suggesting the populations have been homogenized or that there has been substantial gene flow among populations. Additional comparisons among summer-run and fall-run Chinook populations in the upper Columbia River were conducted to determine if there was any differentiation between Chinook with different run timing. These analyses revealed pairwise $\mathrm{F}_{\text {ST }}$ values that were less than 0.01 for the collections of summer Chinook to collections of fall Chinook from Hanford Reach, lower Yakima River, Priest Rapids, and Umatilla. Collections of fall Chinook from Crab Creek, Lyons Ferry Hatchery, Marion Drain, and Snake River had pairwise F $_{\text {ST }}$ values that were higher in comparison to the collections of summer Chinook. The consensus clustering analysis did not provide good statistical support to the groupings, but did show relationships among collections based on geographic proximity. Overall the summer and fall run Chinook that have historically been spawned together were not differentiated while fall Chinook from greater geographic distances were differentiated.

## Proportion of Natural Influence

Another method for assessing the genetic risk of a supplementation program is to determine the influence of the hatchery and natural environments on the adaptation of the composite population. This is estimated by the proportion of natural-origin fish in the hatchery broodstock ( pNOB ) and the proportion of hatchery-origin fish in the natural spawning escapement ( pHOS ). The ratio $\mathrm{pNOB} /(\mathrm{pHOS}+\mathrm{pNOB})$ is the Proportion of Natural Influence (PNI). The larger the ratio ( PNI ), the greater the strength of selection in the natural environment relative to that of the hatchery environment. In order for the natural environment to dominate selection, PNI should be greater than 0.5 (HSRG/WDFW/NWIFC 2004).
For brood years 1989-2009, the PNI was consistently greater than 0.5 (Table 6.26). This indicates that the natural environment has a greater influence on adaptation of Wenatchee summer Chinook than does the hatchery environment.
Table 6.26. Proportionate natural influence (PNI) of the Wenatchee summer Chinook supplementation program for brood years 1989-2009. PNI was calculated as the proportion of naturally produced Chinook in the hatchery broodstock ( pNOB ) divided by the proportion of hatchery Chinook on the spawning grounds ( pHOS ) plus pNOB . $\mathrm{NOS}=$ number of natural-origin Chinook on the spawning grounds; HOS $=$ number of hatchery-origin Chinook on the spawning grounds; $\mathrm{NOB}=$ number of natural-origin Chinook collected for broodstock; and HOB $=$ number of hatchery-origin Chinook included in hatchery broodstock.

| Brood year | Spawners |  |  | Broodstock |  |  | PNI |

## Natural and Hatchery Replacement Rates

Natural replacement rates (NRR) were calculated as the ratio of natural-origin recruits (NOR) to the parent spawning population (spawning escapement). For brood years 1989-2003, NRR for summer Chinook in the Wenatchee averaged 0.96 (range, $0.16-2.90$ ) if harvested fish were not include in the estimate and 2.71 (range, 0.36-9.79) if harvested fish were included in the estimate (Table 6.27). NRRs for more recent brood years will be calculated as soon as all tag recoveries and sampling rates have been loaded into the database.

Hatchery replacement rates (HRR) are the hatchery adult-to-adult returns and were calculated as the ratio of hatchery-origin recruits (HOR) to the parent broodstock collected. These rates should be greater than the NRRs and greater than or equal to 5.30 (the calculated target value in Murdoch and Peven 2005). HRRs exceeded NRRs in 11 of the 15 years of data, regardless if harvest was or was not included in the estimate (Table 6.27). Hatchery replacement rates for Wenatchee summer Chinook have exceeded the estimated target value of 5.30 in three or six of the 15 years of data depending on if harvest was or was not included in the estimate.
Table 6.27. Broodstock collected, spawning escapements, natural and hatchery-origin recruits (NOR and HOR), and natural and hatchery replacement rates (NRR and HRR; with and without harvest) for summer Chinook in the Wenatchee Basin, brood years 1989-2003.

| Brood <br> year | Broodstock <br> Collected | Spawning <br> Escapement | Harvest not included |  |  |  | Harvest included |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  |  |  | 2,149 | 9,133 | 6.21 | 0.64 | 5,062 | 21,489 | 14.63 | 1.50 |
| 1990 |  |  | 88 | 9,463 | 1.01 | 0.87 | 118 | 12,805 | 1.36 | 1.18 |

## Smolt-to-Adult Survivals

Smolt-to-adult survival ratios (SARs) were calculated as the number of hatchery adult recaptures divided by the number of tagged hatchery smolts released. SARs were based on CWT returns. For the available brood years, SARs have ranged from 0.00037 to 0.01696 for hatchery summer Chinook in the Wenatchee basin (Table 6.28).
Table 6.28. Smolt-to-adult ratios (SARs) for Wenatchee hatchery summer Chinook, brood years 19892004.

| Brood year | Number of tagged smolts $_{\text {released }^{\mathbf{a}}}$ | Estimated adult captures $^{\mathbf{b}}$ | SAR |
| :---: | :---: | :---: | :---: |
| 1989 | 144,905 | 1,017 | 0.00702 |
| 1990 | 119,214 | 115 | 0.00096 |
| 1991 | 190,371 | 71 | 0.00037 |
| 1992 | 605,055 | 617 | 0.00102 |
| 1993 | 210,626 | 157 | 0.00075 |
| 1994 | 452,340 | 1,928 | 0.00426 |
| 1995 | 668,409 | 1,539 | 0.00230 |
| 1996 | 585,590 | 567 | 0.00097 |
| 1997 | 434,645 | 7,371 | 0.01696 |
| 1998 | 641,109 | 7,610 | 0.01187 |
| 1999 | 988,328 | 2,487 | 0.00252 |
| 2000 | 903,368 | 13,814 | 0.01528 |
| 2001 | 596,618 | 2,386 | 0.00400 |
| 2002 | 805,919 | 4,319 | 0.00536 |
| 2003 | 639,381 | 3,026 | 0.00473 |
| 2004 | 603,942 | 1,339 | 0.00222 |

| Brood year | Number of tagged smolts <br> released $^{\mathbf{a}}$ | Estimated adult captures $^{\mathbf{b}}$ | SAR |
| :---: | :---: | :---: | :---: |
| Average | 536,864 | 3,023 | 0.00563 |

${ }^{\text {a }}$ Includes all tag codes and CWT released fish (CWT + Ad Clip fish and CWT-only fish).
${ }^{\mathrm{b}}$ Includes estimated recoveries (spawning ground, hatcheries, harvest, etc.) and observed recoveries if estimated recoveries were unavailable.

### 6.8 ESA/HCP Compliance

## Broodstock Collection

Per the 2008 broodstock collection protocol, 492 natural-origin (adipose fin present) summer Chinook adults were targeted for collection at Dryden and Tumwater dams. Because of low wild fish abundance and low trap efficiency at Dryden Dam, the actual 2008 collection totaled 472 summer Chinook ( 400 natural origin and 72 hatchery origin) in combination from Dryden Dam and Tumwater Dam. Trapping began 1 July and ended 8 August 2008.

Summer Chinook and steelhead broodstock collections occurred concurrently at Dryden Dam; therefore, steelhead and spring Chinook encounters at Dryden Dam during Wenatchee summer Chinook broodstock collection were attributable to steelhead broodstock collections authorized under ESA Permit 1395 take authorizations. No steelhead or spring Chinook takes were associated with the Wenatchee summer Chinook collection.

Consistent with impact minimization measures in ESA Permit 1347, all ESA-listed species handled during summer Chinook broodstock collection were subject to water-to-water transfers or anesthetized if removed from water during handling.

## Hatchery Rearing and Release

The 2008 Wenatchee summer Chinook program released an estimated 888,811 smolts, representing $102.9 \%$ of the 864,000 programmed production and was within the $10 \%$ overage allowance identified in ESA permit 1347.

## Hatchery Effluent Monitoring

Per ESA Permits 1196, 1347, and 1395, permit holders shall monitor and report hatchery effluents in compliance with applicable National Pollution Discharge Elimination Systems (NPDES) (EPA 1999) permit limitations. There were no NPDES violations reported at Chelan PUD Hatchery facilities during the period 1 January 2010 through 31 December 2010. NPDES monitoring and reporting for Chelan PUD Hatchery Programs during 2010 are provided in Appendix E.

## Smolt and Emigrant Trapping

ESA-listed spring Chinook and steelhead were encountered during operation of the Lower Wenatchee Trap. ESA takes are reported in the steelhead (Section 3.8) and spring Chinook (Section 5.8) sections and are not repeated here.

## Spawning Surveys

Summer Chinook spawning ground surveys conducted in the Wenatchee Basin during 2010 were consistent with ESA Section 10 Permit No. 1347. Because of the difficulty of quantifying the level of take associated with spawning ground surveys, the Permit does not specify a take level associated with these activities, even though it does authorize implementation of spawning ground surveys. Therefore, no take levels are reported. However, to minimize potential impacts to established redds, wading was restricted to the extent practical, and extreme caution was used to avoid established redds when wading was required.

## SECTION 7: METHOW SUMMER CHINOOK

### 7.1 Broodstock Sampling

This section focuses on results from sampling 2008-2009 Methow summer Chinook broodstock, which were collected in the East Ladder of Wells Dam. Summer Chinook adults collected at Wells Dam are also used in the Okanogan/Similkameen supplementation program. Complete information is not currently available for the 2010 return (this information will be provided in the 2011 annual report).

## Origin of Broodstock

Both 2008 and 2009 broodstock consisted almost entirely of natural-origin (adipose fin present) summer Chinook (Table 7.1). These fish were used for both the Methow and Okanogan supplementation programs. In 2009, to meet production goals, hatchery-origin adults were collected in concert with natural-origin fish. About $1 \%$ of the 2009 broodstock were comprised of hatchery-origin fish (hatchery-origin was determined by examination of scales and CWTs). However, no hatchery fish were incorporated into the broodstock because of pre-spawn mortality.
Table 7.1. Numbers of wild and hatchery summer Chinook collected for broodstock, numbers that died before spawning, and numbers of Chinook spawned for the Methow/Okanogan programs, 1989-2009. Unknown origin fish (i.e., undetermined by scale analysis, no CWT or fin clips, and no additional hatchery marks) were considered naturally produced. Mortality includes fish that died of natural causes typically near the end of spawning and were not needed for the program and surplus fish killed at spawning.

| Brood year | Wild summer Chinook |  |  |  |  | Hatchery summer Chinook |  |  |  |  | Total number spawned |

| 2008 | 418 | 5 | 9 | 404 | 0 | 41 | 0 | 0 | 41 | 0 | 445 |
| 2009 | 553 | 31 | 15 | 507 | 0 | 5 | 5 | 0 | 0 | 0 | 507 |
| Average ${ }^{\text {b }}$ | 488 | 25 | 24 | 431 | 9 | 233 | 11 | 23 | 197 | 5 | 628 |

${ }^{a}$ Number of fish spawned and collected during these years included fish retained from the right- and left-bank ladder traps at Wells Dam and fish collected from the volunteer channel. There was no distinction made between fish collected at trap locations and program (i.e., aggregated population used for Wells, Methow, and Okanogan summer Chinook programs).
${ }^{\mathrm{b}}$ Because of bias from aggregating the spawning population from 1989-1993, averages are based on adult numbers collected from 1994-2006.

## Age/Length Data

Ages of summer Chinook broodstock were determined from analysis of scales and/or CWTs. Broodstock collected from the 2008 return consisted primarily of age- 3 and 4 natural-origin Chinook (85\%) and age-4 and 5 hatchery-origin Chinook (95\%). Age-2, 5, and 6 natural-origin fish collectively made up $15 \%$ of the broodstock (Table 7.2). Age-3 and 6 hatchery-origin Chinook collectively made up $5 \%$ of the broodstock.

Broodstock collected from the 2009 return consisted primarily of age-4 and 5 natural-origin Chinook ( $89 \%$ ) and age-5 hatchery-origin Chinook ( $100 \%$ ). Age-2 and 3 natural-origin fish collectively made up 15\% of the broodstock (Table 7.2). Age-3 and 6 hatchery-origin Chinook collectively made up $11 \%$ of the broodstock (Table 7.2).

Table 7.2. Percent of hatchery and wild summer Chinook of different ages (total age) collected from broodstock for the Methow/Okanogan programs, 1991-2009.

Mean lengths of natural-origin summer Chinook of a given age differed little between 2008 and 2009 (Table 7.3). Average fork lengths for age-5 natural-origin adults were 20 cm longer than that of age- 5 hatchery fish (Table 7.3). These differences may be related to the small sample size of hatchery-origin fish (i.e., few hatchery fish were included in the broodstock).
Table 7.3. Mean fork length (cm) at age (total age) of hatchery and wild Methow/Okanogan summer Chinook collected from broodstock for the Methow/Okanogan programs, 1991-2009; $\mathrm{N}=$ sample size and $\mathrm{SD}=1$ standard deviation.

## Sex Ratios

Male summer Chinook in the 2008 broodstock made up about $49 \%$ of the adults collected, resulting in an overall male to female ratio of 0.94:1.00 (Table 7.4.). In 2009, males made up about $47 \%$ of the adults collected, resulting in an overall male to female ratio of 0.89:1.00 (Table
7.4). The ratio for both 2008 and 2009 broodstock was below the assumed 1:1 ratio goal in the broodstock protocol.

Table 7.4. Numbers of male and female wild and hatchery summer Chinook collected for broodstock at Wells Dam for the Methow/Okanogan programs, 1991-2009. Ratios of males to females are also provided.

${ }^{a}$ Numbers and male to female ratios were derived from the aggregate population collected at Wells Fish Hatchery volunteer channel and left- and right-ladder traps at Wells Dam.
${ }^{\mathrm{b}}$ Total values were derived from 1994-present data to exclude aggregate population bias from 1989-1993 returns.

## Fecundity

Fecundities for the 2008 and 2009 summer Chinook broodstock averaged 4,787 and 5,115 eggs per female, respectively (Table 7.5). These values are close to the overall average of 4,985 eggs per female. Mean observed fecundity for the 2008 return was slightly below the expected fecundity of 5,000 eggs per female assumed in the broodstock protocol; the 2009 return was slightly above the broodstock protocol.

Table 7.5. Mean fecundity of wild, hatchery, and all female summer Chinook collected for broodstock at Wells Dam for the Methow/Okanogan programs, 1989-2009; NA = not available.

### 7.2 Hatchery Rearing

## Rearing History

## Number of eggs taken

Based on the unfertilized egg-to-release survival standard of $81 \%$, a total of 493,827 eggs are needed to meet the program release goal of 400,000 smolts. From 1989 through 2009, the egg take goal was reached in seven of those years (Table 7.6).

Table 7.6. Numbers of eggs taken from summer Chinook broodstock collected at Wells Dam for the Methow/Okanogan programs, 1989-2009.

| Return year | Number of eggs taken |
| :---: | :---: |
| 1989 | 482,800 |
| 1990 | 464,097 |
| 1991 | 586,594 |

| Return year | Number of eggs taken |
| :---: | :---: |
| 1992 | 486,260 |
| 1993 | 531,490 |
| 1994 | 595,390 |

| 2002 | 466,530 |
| 2003 | 473,681 |
| 2004 | 537,210 |
| 2005 | 305,826 |
| 2006 | 509,334 |
| 2007 | 549,802 |
| 2008 | 441,778 |
| 2009 | 560,602 |
| Average | 470,818 |

## Number of acclimation days

Rearing of the 2008 brood Methow summer Chinook was similar to previous years with fish being held on well water before being transferred to Carlton Pond for final acclimation on Methow River water in March 2010 (Table 7.7). Groups of the 1994 and 1995 broods were reared for longer durations at Methow FH on Methow River water.
Table 7.7. Number of days Methow summer Chinook were acclimated at Carlton Pond, brood years 1989-2008.

| Brood year | Release year | Transfer date | Release date | Number of days |
| :---: | :---: | :---: | :---: | :---: |
| 1989 | 1991 | $15-\mathrm{Mar}$ | 6-May | 52 |
| 1990 | 1992 | $26-\mathrm{Feb}$ | $28-\mathrm{Apr}$ | 61 |
| 1991 | 1993 | $10-\mathrm{Mar}$ | $23-\mathrm{Apr}$ | 44 |
| 1992 | 1994 | 4-Mar | $21-\mathrm{Apr}$ | 48 |

| 2007 | 2009 | $18-24-\mathrm{Mar}$ | $21-\mathrm{Apr}$ | $28-34$ |
| 2008 | 2010 | $4-5,8-9-\mathrm{Mar}$ | $4-21-\mathrm{Apr}$ | $33-50$ |

## Release Information

## Numbers released

The 2008 brood Methow summer Chinook program achieved $99.4 \%$ of the 400,000 target goal with about 397,554 fish being forcibly released on 4-21 April 2010 (Table 7.8).
Table 7.8. Numbers of Methow summer Chinook smolts released from the hatchery, brood years 19892008. The release target for Methow summer Chinook is 400,000 smolts.

| Brood year | Release year | CWT mark rate | Number of smolts released |
| :---: | :---: | :---: | :---: |

## Numbers tagged

The 2008 brood Methow summer Chinook were $93.9 \%$ CWT and adipose fin-clipped (Table 7.8).

In 2010, a total of about 5,050 summer Chinook (brood year 2009) were PIT tagged at Eastbank Fish Hatchery on 1-2 September. Fish were not fed during tagging or for two days before and after tagging. Fish averaged 78 mm in length and 5.0 g at time of tagging. As of the end of January 2011, a total of 11 tagged Chinook have died and nine others have shed their tags, leaving 5,030 tagged summer Chinook alive at the end of the month.

Table 7.9 summarizes the number of hatchery summer Chinook that have been PIT-tagged and released into the Methow River.

Table 7.9. Summary of PIT-tagging activities for Methow hatchery summer Chinook, brood years 20082009.

| Brood year | Release year | Number of fish <br> tagged | Number of <br> tagged fish that <br> died | Number of tags <br> shed | Number of <br> tagged fish <br> released |
| :---: | :---: | :---: | :---: | :---: | :---: |

| 2009 | 2011 | 5,050 | NA | NA | NA |

## Fish size and condition at release

Fish were volitionally released as yearling smolts during the period 4-21 April 2010. Size at release of the acclimated population was $88.1 \%$ and $92.5 \%$ of the respective target fork length and weight goals (Table 7.10). This brood year exceeded the CV of length goal by $58 \%$.
Table 7.10. Mean lengths (FL, mm), weight ( g and fish/pound), and coefficient of variation (CV) of Methow summer Chinook smolts released from the hatchery, brood years 1991-2008. Size targets are provided in the last row of the table.

| Brood year | Release year | Fork length (mm) |  | Mean weight |  |
| :---: | :---: | :---: | :---: | :---: | :---: |

## Survival Estimates

Overall survival of the Methow summer Chinook from green (unfertilized) egg-to-release was above the standard set for the program (Table 7.11). This high survival was because of all but one (unfertilized egg-eyed) of the survival categories exceeding the standards set by the program. Currently, it is unknown if gamete viability is gender biased or is uniform between sexes and more influenced by between-year environmental variations.

It is important to note that the Methow summer Chinook program typically receives progeny from the highest ELISA females, while the lowest titer progeny are reserved for the Okanogan program. The inability to effectively manage bacterial kidney disease at Similkameen Pond during the winter months precludes an even mix of progeny for a given brood year between the two programs. As a result, in some years poor survival performance at any level may be more directly related to this procedure than a function of the overall program.
Table 7.11. Hatchery life-stage survival rates (\%) for Methow summer Chinook, brood years 1989-2008. Survival standards or targets are provided in the last row of the table.

| Brood year | Collection to spawning |  | Unfertilized egg-eyed | $\begin{gathered} \text { Eyed } \\ \text { egg- } \\ \text { ponding } \end{gathered}$ | 30 d after ponding |  | Ponding to release | Transport to release | Unfertilized egg-release |

| Standard | 90.0 | 85.0 | $\mathbf{9 2 . 0}$ | $\mathbf{9 8 . 0}$ | $\mathbf{9 7 . 0}$ |  |  |  |  |

${ }^{\text {a }}$ Survival rates were calculated from aggregate population collected at Wells Fish Hatchery volunteer channel and left- and right-ladder traps at Wells Dam.

### 7.3 Disease Monitoring

Results of adult broodstock bacterial kidney disease (BKD) monitoring indicated that most females (99.6\%) had ELISA values less than 0.199. All females had ELISA values less than 0.120 , which means that none of the progeny need to be reared at densities not to exceed 0.06 fish per pound (Table 7.12).

Table 7.12. Proportion of bacterial kidney disease (BKD) titer groups for the Methow/Okanogan summer Chinook broodstock, brood years 1997-2010. Also included are the proportions to be reared at either 0.125 fish per pound or 0.060 fish per pound.

| Brood year $^{\mathbf{a}}$ | Optical density values by titer group |  |  |  | Proportion at rearing densities <br> (fish per pound, fpp) |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |

${ }^{\text {a }}$ Individual ELISA samples were not collected before the 1997 brood.

### 7.4 Spawning Surveys

Surveys for Methow summer Chinook redds were conducted from late September to midNovember, 2010, in the Methow River. Total redd counts (not peak counts) were conducted in the river (see Appendix K for more details).

## Redd Counts

A total of 887 summer Chinook redds were counted in the Methow River in 2010 (Table 7.13). This was higher than the overall average of 614 redds.

Table 7.13. Total number of redds counted in the Methow River, 1989-2010.

| Survey year | Total redd count |
| :---: | :---: |
| 1989 | $149^{*}$ |
| 1990 | $418^{*}$ |
| 1991 | 153 |
| 1992 | 107 |
| 1993 | 154 |
| 1994 | 310 |
| 1995 | 357 |
| 1996 | 181 |

| 1998 | 225 |
| 1999 | 448 |
| 2000 | 500 |
| 2001 | 675 |
| 2002 | 2003 |

| Survey year | Total redd count |
| :---: | :---: |
| 2007 | 620 |
| 2008 | 599 |
| 2009 | 692 |
| 2010 | 887 |
| Average | $\mathbf{6 1 4}$ |

* Total counts based on expanded aerial counts.

## Redd Distribution

Summer Chinook redds were not evenly distributed among the seven reaches in the Methow River. Most redds ( $73 \%$ ) were located in reaches downstream from the town of Twisp and in Reach 5 between Methow Valley Irrigation Diversion (MVID) and the Winthrop Bridge (Table 7.14; Figure 7.1). Few summer Chinook spawned upstream from the Winthrop Bridge in Reaches 6 and 7.

Table 7.14. Total number of summer Chinook redds counted in different reaches on the Methow River during September through early November, 2010. Reach codes are described in Table 2.11.

| Survey reach | Total redd count | Percent |
| :---: | :---: | :---: |
| Methow 1 | 166 | 18.7 |
| Methow 2 | 244 | 27.5 |
| Methow 3 | 236 | 26.6 |
| Methow 4 | 103 | 11.6 |
| Methow 5 | 129 | 14.5 |
| Methow 6 | 5 | 0.6 |
| Methow 7 | 4 | 0.5 |
| Totals | $\mathbf{8 8 7}$ | $\mathbf{1 0 0 . 0}$ |

## Methow Summer Chinook Redds

Figure 7.1. Percent of the total number of summer Chinook redds counted in different reaches on the Methow River during September through mid-November, 2010. Reach codes are described in Table 2.11.

## Spawn Timing

Spawning in 2010 began the last week of September, peaked the second week of October, and ended after the second week of November (Figure 7.2). Stream temperatures in the Methow River, when spawning began, varied from $6.5-12.0^{\circ} \mathrm{C}$. Peak spawning occurred in the upper reaches of the Methow River during the second week of October and in the lower reaches the following week.

## Methow Summer Chinook

Figure 7.2. Number of new summer Chinook redds counted during different weeks in the Methow River, September through mid-November 2010.

## Spawning Escapement

Spawning escapement for Methow summer Chinook was calculated as the total number of redds times the fish per redd ratio estimated from fish sampled at Wells Dam. The estimated fish per redd ratio for Methow summer Chinook in 2010 was 2.81 . Multiplying this ratio by the number of redds counted in the Methow River resulted in a total spawning escapement of 2,492 summer Chinook (Table 7.15).
Table 7.15. Spawning escapements for summer Chinook in the Methow River for return years 19892010.

| Return year | Fish/Redd | Redds | Total spawning escapement |
| :---: | :---: | :---: | :---: |
| $1989^{*}$ | 3.30 | 149 | 492 |
| $1990^{*}$ | 3.40 | 418 | 1,421 |
| $1991^{*}$ | 3.70 | 153 | 566 |
| $1992^{*}$ | 4.30 | 107 | 460 |

| Average | $\mathbf{3 . 0 1}$ | $\mathbf{6 1 4}$ | $\mathbf{1 , 6 5 0}$ |

* Spawning escapement was calculated using the "Modified Meekin Method" (i.e., 3.1 x jack multiplier).

### 7.5 Carcass Surveys

Surveys for Methow summer Chinook carcasses were conducted during late September to midNovember, 2010, in the Methow River (see Appendix K for more details).

## Number sampled

A total of 577 summer Chinook carcasses were sampled during September through midNovember in the Methow River (Table 7.15).

Table 7.15. Numbers of summer Chinook carcasses sampled within each survey reach on the Methow River, 1991-2010. Reach codes are described in Table 2.11.

| Survey <br> year | Number of summer Chinook carcasses |  |  |  |  |  |  |  |

${ }^{\text {a }}$ An additional 113 carcasses were sampled, but reach was not identified.

## Carcass Distribution and Origin

Summer Chinook carcasses were not evenly distributed among reaches within the Methow River in 2010 (Table 7.15; Figure 7.3). Most of the carcasses in the Methow River were found downstream from Twisp.

## Methow Summer Chinook Carcasses

Figure 7.3. Percent of summer Chinook carcasses sampled within different reaches on the Methow River during September through mid-November, 2010. Reach codes are described in Table 2.11.

Numbers of wild and hatchery-origin summer Chinook carcasses sampled in 2010 will be available after analysis of CWTs and scales. Based on the available data (1991-2009), hatchery and wild summer Chinook carcasses were not distributed equally among the reaches in the Methow River (Table 7.16). A larger percentage of hatchery carcasses occurred in the lower reaches, while a larger percentage of wild summer Chinook carcasses occurred in upstream reaches (Figure 7.4).

Table 7.16. Numbers of wild and hatchery summer Chinook carcasses sampled within different reaches on the Methow River, 1991-2010.

| Survey year | Origin | Survey reach |  |  |  |  |  |  | Total |

## Methow Summer Chinook

Figure 7.4. Distribution of wild and hatchery produced carcasses in different reaches on the Methow River, 1993-2009. Reach codes are described in Table 2.11.

## Sampling Rate

Overall, $23 \%$ of the total spawning escapement of summer Chinook in the Methow Basin was sampled in 2010 (Table 7.17). Sampling rates among survey reaches varied from 9 to $36 \%$.
Table 7.17. Number of redds and carcasses, total spawning escapement, and sampling rates for summer Chinook in the Methow Basin, 2010. Reach codes are described in Table 2.11.

| Survey reach | Total number of <br> redds | Total number of <br> carcasses | Total spawning <br> escapement | Sampling rate |
| :---: | :---: | :---: | :---: | :---: |
| Methow 1 | 166 | 105 | 466 | 0.23 |

## Length Data

Mean lengths ( $\mathrm{POH}, \mathrm{cm}$ ) of male and female summer Chinook carcasses sampled during surveys on the Methow River in 2010 are provided in Table 7.18. The average size of males and females sampled in the Methow River were 62 cm and 70 cm , respectively.

Table 7.18. Mean lengths (postorbital-to-hypural length; cm ) and standard deviations (in parentheses) of male and female summer Chinook carcasses sampled in different reaches on the Methow River, 2010. Reach codes are described in Table 2.11.

| Stream/watershed | Mean length (cm) |  |
| :---: | :---: | :---: |
|  | Male | Female |
| Methow 1 | $59.5(9.1)$ | $69.3(6.9)$ |
| Methow 2 | $60.2(10.4)$ | $71.4(5.3)$ |
| Methow 3 | $62.9(9.8)$ | $67.8(6.2)$ |
| Methow 4 | $64.1(9.8)$ | $71.5(7.5)$ |
| Methow 5 | $67.5(8.5)$ | $71.7(4.7)$ |
| Methow 6 | $73.3(2.3)$ | $70.0(1.4)$ |
| Methow 7 | - | $68.0(0.0)$ |
| Total | $\mathbf{6 2 . 0}(\mathbf{1 0 . 0})$ | $\mathbf{6 9 . 8}(\mathbf{6 . 1})$ |

### 7.6 Life History Monitoring

Life history characteristics of Methow summer Chinook were assessed by examining carcasses on spawning grounds and fish collected or examined at broodstock collection sites, and by reviewing tagging data and fisheries statistics.

## Migration Timing

Migration timing of hatchery and wild Methow/Okanogan summer Chinook was determined from broodstock data collected at Wells Dam. Counting of summer/fall Chinook at Wells Dam occurs from 29 June to 15 November. Broodstock collection at the Dam occurs from early July (week 27) to mid-September (week 37) (Table 2.1). Based on broodstock sampling in 2010, both wild and hatchery summer Chinook arrived at Wells Dam about the same time (Table 7.19). This was true throughout most of the migration period. This pattern was also observed when data were pooled for the 2007-2010 survey period.
Table 7.19. The week that $10 \%, 50 \%$ (median), and $90 \%$ of the wild and hatchery summer Chinook salmon passed Wells Dam, 2007-2010. The average week is also provided. Migration timing is based on collection of summer Chinook broodstock at Wells Dam.

| Survey year | Origin | Methow/Okanogan Summer Chinook Migration Time (week) |  |  | Sample size |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  |  | $\mathbf{1 0}$ Percentile | $\mathbf{5 0}$ Percentile | 90 Percentile |  |  |
| 2007 | Wild | 27 | 30 | 34 | 30 | 485 |
|  | Hatchery | 27 | 30 | 33 | 30 | 433 |
| 2008 | Wild | 28 | 30 | 34 | 30 | 542 |
|  | Hatchery | 28 | 30 | 36 | 31 | 884 |
| 2009 | Wild | 27 | 29 | 34 | 30 | 585 |

| Survey year | Origin | Methow/Okanogan Summer Chinook Migration Time (week) |  |  | Sample size |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  |  | $\mathbf{1 0}$ Percentile | $\mathbf{5 0}$ Percentile | $\mathbf{9 0}$ Percentile |  |  |
|  | Hatchery | 27 | 29 | 33 | 29 | 708 |
| 2010 | Wild | 27 | 29 | 33 | 29 | 377 |
|  | Hatchery | 27 | 29 | 32 | 29 | 801 |
|  | Wild | 27 | 29 | $\mathbf{3 4}$ | $\mathbf{3 0}$ | $\mathbf{1 , 9 8 9}$ |
|  | Hatchery | 27 | 29 | $\mathbf{3 4}$ | $\mathbf{3 0}$ | $\mathbf{2 9 , 8 2 6}$ |

## Age at Maturity

Most of the wild and hatchery summer Chinook sampled during the period 1993-2009 in the Methow River were age-4 and 5 fish (total age) (Table 7.20; Figure 7.5). A higher percentage of age- 4 wild Chinook returned to the basin than did age- 4 hatchery Chinook. In contrast, a higher proportion of age- 6 hatchery fish returned than did age- 6 wild fish. Thus, a higher percentage of hatchery fish returned at an older age than did wild fish.
Table 7.20. Proportions of wild and hatchery summer Chinook of different ages (total age) sampled on spawning grounds in the Methow River, 1993-2009.

Methow Summer Chinook

Figure 7.5. Proportions of wild and hatchery summer Chinook of different total ages sampled at broodstock collection sites and on spawning grounds in the Methow River for the combined years 19932009.

## Size at Maturity

On average, hatchery summer Chinook were about 4 cm smaller than wild summer Chinook sampled in the Methow Basin (Table 7.21). This is interesting given that a slightly higher percentage of hatchery fish returned as age-6 fish than did wild fish. Future analyses will compare sizes of hatchery and wild fish of the same age groups and gender.

Table 7.21. Mean lengths ( $\mathrm{POH} ; \mathrm{cm}$ ) and variability statistics for wild and hatchery summer Chinook sampled in the Methow Basin, 1993-2009; SD = 1 standard deviation.

## Contribution to Fisheries

Most of the harvest on hatchery-origin Methow summer Chinook occurred in the Ocean (Table 7.22). Ocean harvest has made up $13 \%$ to $99 \%$ of all hatchery-origin Methow summer Chinook harvested. Brood years 1989 and 1998 provided the largest harvests, while brood years 1996 and 1999 provided the lowest.
Table 7.22. Estimated number and percent (in parentheses) of hatchery-origin Methow summer Chinook captured in different fisheries, brood years 1989-2004.

## Straying

Stray rates were determined by examining CWTs recovered on spawning grounds within and outside the Methow Basin. Targets for strays based on return year (recovery year) and brood year should be less than $5 \%$.

Rates of hatchery-origin Methow summer Chinook straying into basins outside the Methow have been very low (Table 7.23). Although a few hatchery-origin Methow summer Chinook have strayed into the Okanogan Basin, Entiat Basin, Chelan tailrace, and Hanford Reach, staying has consistently been less than $5 \%$.

Table 7.23. Number and percent of spawning escapements within other non-target basins that consisted of hatchery-origin Methow summer Chinook, return years 1994-2007. For example, for return year 2002, $0.4 \%$ of the summer Chinook escapement in the Okanogan Basin consisted of hatchery-origin Methow summer Chinook. Percent strays should be less than $5 \%$.

| Return year | Wenatchee |  | Okanogan |  | Chelan |  | Entiat |  | Hanford Reach |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |

| $1999$ | 0 | 0.0 | 6 | 0.2 | 0 | 0.0 | 0 | 0.0 | 7 | 0.0 |
| 2000 | 0 | $0.0$ | 3 | 0.1 | 0 | 0.0 | 0 | 0.0 | 0 | 0.0 |
| 2001 | 0 | 0.0 | 0 | 0.0 | 0 | 0.0 | 0 | 0.0 | 7 | 0.0 |
| 2002 | 0 | 0.0 | 54 | 0.4 | 0 | 0.0 | 0 | 0.0 | 0 | 0.0 |
| 2003 | 0 | 0.0 | 1 | 0.0 | 6 | 1.4 | 0 | 0.0 | 0 | 0.0 |
| 2004 | 0 | 0.0 | 7 | 0.1 | 3 | 0.7 | 0 | 0.0 | 0 | 0.0 |
| 2005 | 0 | 0.0 | 24 | 0.3 | 0 | 0.0 | 0 | 0.0 | 0 | 0.0 |
| 2006 | 0 | 0.0 | 12 | 0.1 | 0 | 0.0 | 0 | 0.0 | 0 | 0.0 |
| 2007 | 0 | 0.0 | 17 | 0.4 | 2 | 1.1 | 1 | 0.4 | 0 | 0.0 |
| Total | 0 | 0.0 | 205 | 0.3 | 11 | 0.3 | 1 | 0.0 | 14 | 0.0 |

On average, about $4.0 \%$ of the returns have strayed into non-target spawning areas, falling below the target of $5 \%$ (Table 7.24). Depending on brood year, percent strays into non-target spawning areas have ranged from $0-14.7 \%$. Few ( $<2 \%$ on average) have strayed into non-target hatchery programs.

Table 7.24. Number and percent of hatchery-origin Methow summer Chinook that homed to target spawning areas and the target hatchery program, and number and percent that strayed to non-target spawning areas and non-target hatchery programs, by brood years 1989-2004. Percent stays should be less than 5\%.

## Genetics

Genetic studies were conducted to investigate relationships among temporally replicated collections of summer Chinook from the Wenatchee River, Methow River, and Okanogan River in the upper Columbia River basin (Kassler et al. 2100; the entire report is appended as Appendix J). Samples from the Eastbank Hatchery - Wenatchee stock, Eastbank Hatchery Methow/Okanogan (MEOK) stock, and Wells Hatchery were also included in the analysis. Samples of natural and hatchery-origin summer Chinook were analyzed and compared to determine if the supplementation program has affected the genetic structure of these populations. The study also calculated the effective number of breeders for collection locations of natural and hatchery-origin summer Chinook from 1993 and 2008.

In general, population differentiation was not observed among the temporally replicated collection locations. A single collection from the Okanogan River (1993) was the only collection showing statistically significant differences. The effective number of breeders was not statistically different from the early collection in 1993 in comparison to the late collection in 2008. Overall, these analyses revealed a lack of differentiation among the temporal replicates from the same locations and among the collection from different locations, suggesting the populations have been homogenized or that there has been substantial gene flow among populations. Additional comparisons among summer-run and fall-run Chinook populations in the upper Columbia River were conducted to determine if there was any differentiation between Chinook with different run timing. These analyses revealed pairwise $\mathrm{F}_{\mathrm{ST}}$ values that were less than 0.01 for the collections of summer Chinook to collections of fall Chinook from Hanford Reach, lower Yakima River, Priest Rapids, and Umatilla. Collections of fall Chinook from Crab Creek, Lyons Ferry Hatchery, Marion Drain, and Snake River had pairwise $\mathrm{F}_{\text {ST }}$ values that were higher in comparison to the collections of summer Chinook. The consensus clustering analysis did not provide good statistical support to the groupings, but did show relationships among collections based on geographic proximity. Overall the summer and fall run Chinook that have historically been spawned together were not differentiated while fall Chinook from greater geographic distances were differentiated.

## Proportion of Natural Influence

Another method for assessing the genetic risk of a supplementation program is to determine the influence of the hatchery and natural environments on the adaptation of the composite population. This is estimated by the proportion of natural-origin fish in the hatchery broodstock ( pNOB ) and the proportion of hatchery-origin fish in the natural spawning escapement ( pHOS ). The ratio $\mathrm{pNOB} /(\mathrm{pHOS}+\mathrm{pNOB})$ is the Proportion of Natural Influence (PNI). The larger the ratio (PNI), the greater the strength of selection in the natural environment relative to that of the hatchery environment. In order for the natural environment to dominate selection, PNI should be greater than 0.5 (HSRG/WDFW/NWIFC 2004).

For brood years 1989-2009, the PNI was equal to or greater than 0.5 in all but three years (Table 7.25). This indicates that the natural environment has a greater influence on adaptation of Methow summer Chinook than does the hatchery environment.
Table 7.25. Proportionate natural influence (PNI) of the Methow summer Chinook supplementation program for brood years 1989-2009. PNI was calculated as the proportion of naturally produced Chinook in the hatchery broodstock ( pNOB ) divided by the proportion of hatchery Chinook on the spawning grounds (pHOS) plus pNOB. NOS = number of natural-origin Chinook on the spawning grounds; HOS = number of hatchery-origin Chinook on the spawning grounds; NOB = number of natural-origin Chinook collected for broodstock; and HOB = number of hatchery-origin Chinook included in hatchery broodstock.

| Brood year | Spawners |  |  | Broodstock |  |  | PNI |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  | NOS | HOS | pHOS | NOB | HOB | pNOB |  |

| Average | 1,018 | 591 | 0.32 | 433 | 197 | 0.66 | 0.68 |

## Natural and Hatchery Replacement Rates

Natural replacement rates (NRR) were calculated as the ratio of natural-origin recruits (NOR) to the parent spawning population (spawning escapement). For brood years 1989-2003, NRR for summer Chinook in the Methow averaged 1.22 (range, 0.10-4.74) if harvested fish were not include in the estimate and 2.38 (range, $0.18-10.52$ ) if harvested fish were included in the estimate (Table 7.26). NRRs for more recent brood years will be calculated as soon as all tag recoveries and sampling rates have been loaded into the database.

Hatchery replacement rates (HRR) are the hatchery adult-to-adult returns and were calculated as the ratio of hatchery-origin recruits (HOR) to the parent broodstock collected. These rates should be greater than the NRRs and greater than or equal to 5.30 (the calculated target value in Murdoch and Peven 2005). HRRs exceeded NRRs in eight out of the 15 years of data, regardless if harvest was or was not included in the estimate (Table 7.26). Hatchery replacement rates for Methow summer Chinook have exceeded the estimated target value of 5.30 in two of the 15 years of data, regardless if harvest is or is not included in the estimate.
Table 7.26. Broodstock collected, spawning escapements, natural and hatchery-origin recruits (NOR and HOR), and natural and hatchery replacement rates (NRR and HRR; with and without harvest) for wild summer Chinook in the Methow Basin, brood years 1989-2003.

| Brood year | Broodstock Collected | Spawning Escapement | Harvest not included |  |  |  | Harvest included |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  |  |  | HOR | NOR | HRR | NRR | HOR | NOR | HRR | NRR |
| 1989 | 202 | 492 | 1,389 | 620 | 6.88 | 1.26 | 3,396 | 1,509 | 16.81 | 3.07 |
| 1990 | 202 | 1,421 | 282 | 933 | 1.40 | 0.66 | 386 | 1,285 | 1.91 | 0.90 |
| 1991 | 266 | 566 | 125 | 276 | 0.47 | 0.49 | 186 | 413 | 0.70 | 0.73 |
| 1992 | 214 | 460 | 108 | 598 | 0.50 | 1.30 | 139 | 772 | 0.65 | 1.68 |
| 1993 | 234 | 508 | 38 | 420 | 0.16 | 0.83 | 62 | 685 | 0.26 | 1.35 |
| 1994 | 260 | 1,085 | 526 | 521 | 2.02 | 0.48 | 715 | 710 | 2.75 | 0.65 |
| 1995 | 242 | 1,214 | 154 | 1,149 | 0.64 | 0.95 | 232 | 1,730 | 0.96 | 1.43 |
| 1996 | 220 | 615 | 61 | 420 | 0.28 | 0.68 | 75 | 518 | 0.34 | 0.84 |
| 1997 | 209 | 697 | 404 | 1,448 | 1.93 | 2.08 | 653 | 2,351 | 3.12 | 3.37 |
| 1998 | 235 | 675 | 1,745 | 3,202 | 7.43 | 4.74 | 3,858 | 7,100 | 16.42 | 10.52 |
| 1999 | 222 | 986 | 18 | 2,827 | 0.08 | 2.87 | 33 | 5,187 | 0.15 | 5.26 |

| 2003 | 224 | 3,930 | 118 | 397 | 0.53 | 0.10 | 213 | 717 | 0.95 | 0.18 |
| Average | 226 | 1,416 | 391 | 1,170 | 1.76 | 1.22 | 836 | 2,465 | 3.78 | 2.38 |

## Smolt-to-Adult Survivals

Smolt-to-adult survival ratios (SARs) were calculated as the number of hatchery adult recaptures divided by the number of tagged hatchery smolts released. SARs were based on CWT returns. For the available brood years, SARs have ranged from 0.00008 to 0.01888 for hatchery summer Chinook in the Methow Basin (Table 7.27).

Table 7.27. Smolt-to-adult ratios (SARs) for Methow summer Chinook, brood years 1989-2004.

| Brood year | Number of tagged smolts <br> released $^{\mathbf{a}}$ | Estimated adult captures $^{\mathbf{b}}$ | SAR |
| :---: | :---: | :---: | :---: |
| 1989 | 358,237 | 2,882 | 0.00804 |
| 1990 | 371,483 | 369 | 0.00099 |
| 1991 | 377,097 | 130 | 0.00034 |
| 1992 | 392,636 | 138 | 0.00035 |
| 1993 | 200,345 | 62 | 0.00031 |
| 1994 | 400,488 | 710 | 0.00177 |
| 1995 | 344,974 | 229 | 0.00066 |
| 1996 | 289,880 | 74 | 0.00026 |
| 1997 | 380,430 | 649 | 0.00171 |
| 1998 | 202,559 | 3,824 | 0.01888 |
| 1999 | 422,473 | 33 | 0.00008 |
| 2000 | 334,337 | 768 | 0.00230 |
| 2001 | 246,159 | 923 | 0.00375 |
| 2002 | 310,846 | 890 | 0.00286 |
| 2003 | 353,495 | 213 | 0.00060 |
| 2004 | 394,490 | 293,246 | 762 |
| Average |  |  | 0.00074 |

${ }^{\text {a }}$ Includes all tag codes and CWT released fish (CWT + Ad Clip fish and CWT-only fish).
${ }^{\mathrm{b}}$ Includes estimated recoveries (spawning ground, hatcheries, harvest, etc.) and observed recoveries if estimated recoveries were unavailable.

### 7.7 ESA/HCP Compliance

## Broodstock Collection

Summer Chinook adults collected at Wells Dam are used for both the Methow and Okanogan supplementation programs. Per the 2008 broodstock collection protocol, 556 natural-origin (adipose fin present) adults were targeted for collection between 1 July and 14 September at the East Ladder of Wells Dam. Actual collections occurred between 2 July and 10 September and totaled 459 summer Chinook. ESA Permit 1347 provides authorization to collect Methow and Okanogan summer Chinook at Wells Dam three days per week and up to 16 hours per day from July through November. During 2008, broodstock collection activities encompassed a total of 32 days, representing $100 \%$ of the allowable trapping days allowed under ESA Permit 1347.

Collection of Methow and Okanogan summer Chinook broodstock at Wells Dam occurred concurrently with collection of summer steelhead for the Wells steelhead program authorized under ESA Section 10 Permit 1395. Encounters with steelhead and spring Chinook during Methow and Okanogan summer Chinook broodstock collections did not result in takes that were outside those authorized in Permit 1347 and in Permit 1395 for the Wells Steelhead program. Steelhead encountered during summer Chinook collections that were not required for steelhead broodstock were passed at the trap site and were not physically handled. Any spring Chinook encountered during summer Chinook broodstock activities were also passed without handling.

Hatchery Rearing and Release
The 2008 brood Methow/Okanogan summer Chinook reared throughout their juvenile life-stages at Eastbank Fish Hatchery and the Carlton Acclimation pond without incident (see Section 7.2). The 2008 brood smolt release totaled 397,554 summer Chinook, representing $99.4 \%$ of the production objective and was compliant with the $10 \%$ overage allowable in ESA Section 10 Permit 1347.

## Hatchery Effluent Monitoring

Per ESA Permits 1196, 1347, and 1395, permit holders shall monitor and report hatchery effluents in compliance with applicable National Pollution Discharge Elimination Systems (NPDES) (EPA 1999) permit limitations. There were no NPDES violations reported at Chelan PUD Hatchery facilities during the period 1 January 2010 through 31 December 2010. NPDES monitoring and reporting for Chelan PUD Hatchery Programs during 2010 are provided in Appendix E.

## Spawning Surveys

Summer Chinook spawning ground surveys conducted in the Methow Basin during 2010 were consistent with ESA Section 10 Permit No. 1347. Because of the difficulty of quantifying the level of take associated with spawning ground surveys, the Permit does not specify a take level associated with these activities, even though it does authorize implementation of spawning ground surveys. Therefore, no take levels are reported. However, to minimize potential impacts to established redds, wading was restricted to the extent practical, and extreme caution was used to avoid established redds when wading was required.

## SECTION 8: OKANOGAN/SIMILKAMEEN SUMMER CHINOOK

### 8.1 Broodstock Sampling

Summer Chinook broodstock for the Okanogan/Similkameen and Methow programs is collected in the East Ladder of Wells Dam. Refer to Section 7.1 for information on the origin, age and length, sex ratios, and fecundity of summer Chinook broodstock collected at Wells Dam.

### 8.2 Hatchery Rearing

## Rearing History

## Number of eggs taken

Based on the unfertilized egg-to-release survival standard of $81 \%$, a total of 711,111 eggs are required to meet the program release goal of 576,000 smolts. From 1989 through 2009, the egg take goal was reached in 12 of those years (Table 8.1).
Table 8.1. Numbers of eggs taken from summer Chinook broodstock collected at Wells Dam for the Okanogan program, 1989-2009.

| Return year | Number of eggs taken |
| :---: | :---: |
| 1989 | 724,200 |
| 1990 | 696,144 |
| 1991 | 879,892 |
| 1992 | 729,389 |
| 1993 | 797,234 |
| 1994 | 893,086 |
| 1995 | 736,500 |
| 1996 | 672,000 |
| 1997 | 601,744 |
| 1998 | 584,018 |
| 1999 | 725,589 |
| 2000 | 645,403 |
| 2001 | 418,907 |
| 2002 | 718,599 |
| 2003 | 710,521 |
| 2004 | 805,814 |
| 2005 | 452,928 |
| 2006 | 757,350 |
| 2007 | 824,703 |
| 2008 | 662,668 |
| 2009 | 840,902 |
| Average | 708,457 |

## Number of acclimation days

Summer Chinook were released volitionally from Similkameen Pond as yearling smolts beginning in April and ending in May 2010. Fish acclimated at Similkameen were held for 176 to 201 days (Table 8.2). Summer Chinook at Bonaparte Pond were released volitionally between 19 April and 5 May. Fish acclimated at Bonaparte Pond were held for 165-185 days before release.

Table 8.2. Number of days Okanogan summer Chinook broods were acclimated at Similkameen and Bonaparte ponds, brood years 1989-2008.

| Brood year | Release year | Rearing facility | Transfer date | Release date | Number of days |
| :---: | :---: | :---: | :---: | :---: | :---: |
| 1989 | 1991 | Similkameen | 29-Oct | 7-May | 190 |
| 1990 | 1992 | Similkameen | 5-Nov | 25-Apr | 171 |
| 1991 | 1993 | Similkameen | 1-Nov | 9-Apr | 159 |
| 1992 | 1994 | Similkameen | 2-Nov | 1-Apr | 150 |
|  |  |  | 26-Feb | 1-Apr | 34 |
| 1993 | 1995 | Similkameen | 24-Oct | 1-Apr | 159 |
|  |  |  | 24-Feb | 1-Apr | 36 |
| 1994 | 1996 | Similkameen | 30-Oct | 6-Apr | 158 |
|  |  |  | 14-Mar | 6-Apr | 23 |
| 1995 | 1997 | Similkameen | 1-Oct | 1-Apr | 182 |
| 1996 | 1998 | Similkameen | 10-Oct | 15-Mar | 156 |
| 1997 | 1999 | Similkameen | 7-Oct | 19-Apr | 194 |
| 1998 | 2000 | Similkameen | 5-Oct | 19-Apr | 196 |
| 1999 | 2001 | Similkameen | 5-Oct | 18-Apr | 195 |
| 2000 | 2002 | Similkameen | 10-Oct | 8-Apr | 180 |
| 2001 | 2003 | Similkameen | 1-Oct | 29-Apr | 210 |
| 2002 | 2004 | Similkameen | 9-Nov | 23-Apr | 165 |
| 2003 | 2005 | Similkameen | 19-Oct | 28-Apr | 191 |
| 2004 | 2006 | Similkameen | 26-Oct | 23-Apr | 179 |
| 2005 | 2007 | Bonaparte | 6-Nov | 11-Apr | 156 |
|  |  | Similkameen | 25-Oct | 18-Apr - 9-May | 179-200 |
| 2006 | 2008 | Similkameen | 15-17-Oct | 16-Apr - 7-May | 182-205 |
| 2007 | 2009 | Bonaparte | 3-4-Nov | 10-22-Apr | 157-170 |
|  |  | Similkameen | 20-24-Oct | 14-Apr - 9-May | 172-201 |
| 2008 | 2010 | Bonaparte | 2-4-Nov | 19-Apr - 5-May | 167-185 |

| Brood year | Release year | Rearing facility | Transfer date | Release date | Number of days |
| :---: | :---: | :---: | :---: | :---: | :---: |
|  |  | Similkameen | $26-28-\mathrm{Oct}$ | $19-\mathrm{Apr}-14-\mathrm{May}$ | $176-201$ |

## Release Information

## Numbers released

The 2008 Okanogan summer Chinook program achieved $90.2 \%$ of the 576,000 target goal with about 519,357 fish being released volitionally in the Similkameen and Okanogan rivers. About 175,729 summer Chinook were released volitionally from the Bonaparte Pond between 19 April and 5 May, while 343,628 fish were released volitionally from the Similkameen facility between 19 April and 14 May (Table 8.3).

Table 8.3. Numbers of Okanogan summer Chinook smolts released from the Similkameen and Bonaparte ponds, brood years 1989-2008; NA = not available. The release target for Okanogan summer Chinook is 576,000 smolts.

| Brood year | Release year | Rearing facility | CWT mark rate | Number of smolts released |
| :---: | :---: | :---: | :---: | :---: |
| 1989 | 1991 | Similkameen | 0.5732 | 352,600 |
| 1990 | 1992 | Similkameen | 0.6800 | 540,000 |
| 1991 | 1993 | Similkameen | 0.5335 | 675,500 |

|  |  | Similkameen | 0.9947 | 343,628 |
| Average |  |  | 0.8476 | 458,693 |

## Numbers tagged

The 2008 brood Okanogan summer Chinook from the Similkameen and Bonaparte facilities were respectively $99.5 \%$ CWT and adipose fin-clipped (Table 8.3).

In 2010, a total of about 5,100 Similkameen summer Chinook (brood year 2009) were PIT tagged at Eastbank Fish Hatchery on 26-28 July. Fish were not fed during tagging or for two days before and after tagging. Fish averaged 69 mm in length and 3.8 g at time of tagging. As of the end of January 2011, a total of 11 tagged Chinook have died; no fish have shed their tags. These left 5,030 tagged summer Chinook alive at the end of the month.

Table 8.4 summarizes the number of hatchery summer Chinook that have been PIT-tagged and released into the Okanogan Basin.
Table 8.4. Summary of PIT-tagging activities for Okanogan hatchery summer Chinook, brood years 2008-2009.

| Brood year | Release year | Number of fish <br> tagged | Number of <br> tagged fish that <br> died | Number of tags <br> shed | Number of <br> tagged fish <br> released |
| :---: | :---: | :---: | :---: | :---: | :---: |
| 2008 | 2010 | 5,700 (high density) | 1,169 | 0 | 4,531 |
|  |  | 1,407 | 0 | 4,293 |  |
| 2009 | 2011 | 5,100 | NA | NA | NA |

## Fish size and condition at release

Size at release of the Similkameen population was $79.5 \%$ and $77.3 \%$ of the target fork length and weight, respectively. The target CV for fork length was exceeded by $37 \%$ (Table 8.5). No information was available for the Bonaparte acclimation group.

Table 8.5. Mean lengths (FL, mm), weight ( g and fish/pound), and coefficient of variation (CV) of Okanogan summer Chinook smolts released from the hatchery, brood years 1989-2008. Size targets are provided in the last row of the table.

| Brood year | Release year | Fork length (mm) |  | Mean weight |  |
| :---: | :---: | :---: | :---: | :---: | :---: |

| Targets |  | 176 | 9.0 | 45.4 | 10 |

## Survival Estimates

Overall survival of Okanogan summer Chinook from green (unfertilized) egg to release was below the standard set for the program (Table 8.6). Lower than expected transport-to-release survival had the greatest effect on the overall survival performance. Currently, it is unknown if gamete viability is gender biased or is uniform between sexes and more influenced by betweenyear environmental variations.
Table 8.6. Hatchery life-stage survival rates (\%) for Okanogan summer Chinook, brood years 1989-2008. Survival standards or targets are provided in the last row of the table.

| Brood year | Rearing facility | Collection to spawning |  | Unfertilized egg-eyed | Eyed <br> eggponding | 30 d <br> after ponding | $100 \mathrm{~d}$ <br> after ponding | $\begin{aligned} & \text { Ponding } \\ & \text { to } \\ & \text { release } \end{aligned}$ | Transport to release | Unfertilized egg-release |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |

${ }^{\mathrm{a}}$ Survival rates were calculated from the aggregate population collected at Wells Fish Hatchery volunteer channel and left- and right-ladder traps at Wells Dam.

### 8.3 Disease Monitoring

Rearing of the 2008 brood Okanogan summer Chinook was similar to previous years with fish being held on well water before being transferred for final acclimation on Similkameen or Okanogan river water. The Similkameen and Bonaparte groups were transferred in late October and early November, respectively. The Bonaparte group began developing bacterial gill disease infections in December 2009. No further problems developed after treatment. Fish acclimating at the Similkameen facility were diagnosed with having an external fungus and bacterial gill disease in November. They were treated through March with minimal results. No further problems developed after treatment. It was believed but not confirmed that considerable mortality was possibly due to a low level influx of toxins associated with increased runoff. No additional disease-related problems were noted before the fish were released.
Results of adult broodstock bacterial kidney disease (BKD) monitoring for Methow/Okanogan summer Chinook are shown in Table 7.11 in Section 7.3.

### 8.4 Spawning Surveys

Surveys for Okanogan/Similkameen summer Chinook redds were conducted from late September to mid-November, 2010, in the Okanogan and Similkameen rivers. Total redd counts (not peak counts) were conducted in the rivers (see Appendix K for more details).

## Redd Counts

A total of 2,118 summer Chinook redds were counted in the Okanogan Basin in 2010 (Table 8.7). This was greater than the overall average of 1,721 redds.

Table 8.7. Total number of redds counted in the Okanogan Basin, 1989-2010.

| Survey year | Number of summer Chinook redds |  |  |
| :---: | :---: | :---: | :---: |

| 2009 | 1,672 | 1,298 | 2,970 |
| 2010 | 1,011 | 1,107 | 2,118 |
| Average | 815 | $\mathbf{9 0 6}$ | $\mathbf{1 , 7 2 1}$ |

* Reach-expanded aerial counts.

## Redd Distribution

Summer Chinook redds were not evenly distributed among the survey reaches in the Okanogan Basin. Most redds ( $90 \%$ ) were located in the upper Okanogan and lower Similkameen reaches (reaches upstream of the Riverside Bridge) (Table 8.8; Figure 8.1). Relatively few summer Chinook spawned downstream of the Riverside Bridge on the Okanogan River (Reaches 1-4).
Table 8.8. Total number of summer Chinook redds counted in different reaches in the Okanogan Basin during September through mid-November, 2010. Reach codes are described in Table 2.11.

| Survey reach | Total redd count | Percent |
| :---: | :---: | :---: |
| Okanogan 1 | 9 | 0.004 |
| Okanogan 2 | 58 | 0.027 |
| Okanogan 3 | 67 | 0.032 |
| Okanogan 4 | 89 | 0.042 |
| Okanogan 5 | 357 | 0.169 |
| Okanogan 6 | 431 | 0.203 |
| Similkameen 1 | 895 | 0.423 |
| Similkameen 2 | 212 | 0.100 |
| Totals | $\mathbf{2 , 1 1 8}$ | $\mathbf{1 . 0 0 0}$ |

## Okan/Similk Summer Chinook Redds

Figure 8.1. Percent of the total number of summer Chinook redds counted in different reaches in the Okanogan Basin during September through mid-November, 2010. Reach codes are described in Table 2.11 .

## Spawn Timing

Spawning in 2010 began the last week of September in the Similkameen and Okanogan rivers, and peaked during the second week of October in both rivers (Figure 8.2). Spawning began when stream temperature varied from $8.5-16^{\circ} \mathrm{C}$.

## Okan/Similk Summer Chinook

Figure 8.2. Number of new summer Chinook redds counted during different weeks in the Okanogan Basin, September through mid-November, 2010.

## Spawning Escapement

Spawning escapement for Okanogan/Similkameen summer Chinook was calculated as the total number of redds times the fish per redd ratio estimated from fish sampled at Wells Dam. The estimated fish per redd ratio for Okanogan/Similkameen summer Chinook in 2010 was 2.81. Multiplying this ratio by the number of redds counted in the Okanogan and Similkameen rivers resulted in a total spawning escapement of 5,952 summer Chinook (Table 8.9).
Table 8.9. Spawning escapements for summer Chinook in the Okanogan and Similkameen rivers for return years 1989-2010.

| Return year | Fish/Redd | Spawning escapement |  |  |
| :---: | :---: | :---: | :---: | :---: |

* Spawning escapement was calculated using the "Modified Meekin Method" (i.e., $3.1 \times$ jack multiplier).

### 8.5 Carcass Surveys

Surveys for summer Chinook carcasses were conducted during late September to midNovember, 2010, in the Okanogan and Similkameen rivers (see Appendix K for more details).

## Number sampled

A total of 1,453 summer Chinook carcasses were sampled during September through midNovember in the Okanogan Basin (Table 8.10). A total of 678 were sampled in the Okanogan River and 775 in the Similkameen River.

Table 8.10. Numbers of summer Chinook carcasses sampled within each survey reach in the Okanogan Basin, 1993-2010. Reach codes are described in Table 2.11.

| Survey year | Number of summer Chinook carcasses |  |  |  |  |  |  |  |  |

| Average | 1 | 6 | 29 | 14 | 136 | 224 | 610 | 94 | 1,116 |

${ }^{\text {a }} 25$ additional carcasses were sampled on the Similkameen and 46 on the Okanogan without any reach designation.
${ }^{\mathrm{b}}$ One additional carcasses was sampled on the Similkameen without any reach designation.
${ }^{\text {c }} 793$ carcasses were sampled on the Similkameen before initiation of spawning (pre-spawn mortality) and an additional 40 carcasses were sampled on the Okanogan. The cause of the high mortality (Ichthyophthirius multifilis and Flavobacterium columnarae) was exacerbated by high river temperatures.

## Carcass Distribution and Origin

Summer Chinook carcasses were not evenly distributed among reaches within the Okanogan Basin in 2010 (Table 8.9; Figure 8.3). Most of the carcasses in the basin were found in the upper Okanogan River and lower Similkameen River. The highest percentage of carcasses (43\%) was sampled in Reach 1 on the Similkameen River between the Driscoll Channel and Oroville Bridge.

Figure 8.3. Percent of summer Chinook carcasses sampled within different reaches in the Okanogan Basin during September through mid-November, 2010. Reach codes are described in Table 2.11.

Numbers of wild and hatchery-origin summer Chinook carcasses sampled in 2010 will be available after analysis of CWTs and scales. Based on the available data (1991-2009), most fish, regardless of origin, were found in Reach 1 on the Similkameen River (Driscoll Channel to Oroville Bridge) (Table 8.11). However, a slightly larger percentage of hatchery fish were found in reaches on the Similkameen River than were wild fish (Figure 8.4). In contrast, a larger percentage of wild fish were found in reaches on the Okanogan River.

Table 8.11. Numbers of wild and hatchery summer Chinook carcasses sampled within different reaches in the Okanogan Basin, 1993-2009.

| Survey year | Origin | Survey reach |  |  |  |  |  |  |  | Total |

## Okan/Similk Summer Chinook

Figure 8.4. Distribution of wild and hatchery produced carcasses in different reaches in the Okanogan Basin, 1993-2009. Reach codes are described in Table 2.11.

## Sampling Rate

Overall, $24 \%$ of the total spawning escapement of summer Chinook in the Okanogan Basin was sampled in 2010 (Table 8.12). This was above the target of $20 \%$. Sampling rates among survey reaches varied from 6 to $29 \%$.

Table 8.12. Number of redds and carcasses, total spawning escapement, and sampling rates for summer Chinook in the Okanogan Basin, 2010.

| Sampling reach | Total number of <br> redds | Total number of <br> carcasses | Total spawning <br> escapement | Sampling rate |
| :---: | :---: | :---: | :---: | :---: |
| Okanogan 1 | 9 | 3 | 26 | 0.12 |
| Okanogan 2 | 58 | 10 | 163 | 0.06 |
| Okanogan 3 | 67 | 30 | 188 | 0.16 |

| Okanogan 5 | 357 | 241 | 1,003 | 0.24 |
| Okanogan 6 | 431 | 352 | 1,211 | 0.29 |
| Similkameen 1 | 895 | 627 | 2,515 | 0.25 |

| Sampling reach | Total number of <br> redds | Total number of <br> carcasses | Total spawning <br> escapement | Sampling rate |
| :---: | :---: | :---: | :---: | :---: |
| Similkameen 2 | 212 | 148 | 596 | 0.25 |
| Total | 2,118 | 1,453 | 5,952 | 0.24 |

## Length Data

Mean lengths ( $\mathrm{POH}, \mathrm{cm}$ ) of male and female summer Chinook carcasses sampled during surveys on the Okanogan and Similkameen rives in 2010 are provided in Table 8.13. The average size of males and females sampled in the Okanogan Basin were 63 cm and 72 cm , respectively.
Table 8.13. Mean lengths (postorbital-to-hypural length; cm ) and standard deviations (in parentheses) of male and female summer Chinook carcasses sampled in different reaches in the Okanogan Basin, 2010.

| Stream/watershed | Mean length (cm) |  |
| :---: | :---: | :---: |
|  | Male | Female |
| Okanogan 1 | $57.3(4.2)$ | - |
| Okanogan 2 | $55.8(8.6)$ | $68.0(4.9)$ |
| Okanogan 3 | $58.9(7.4)$ | $73.7(5.4)$ |
| Okanogan 4 | $59.7(6.4)$ | $70.6(5.5)$ |
| Okanogan 5 | $64.7(10.2)$ | $69.7(6.0)$ |
| Okanogan 6 | $60.1(9.6)$ | $70.0(5.8)$ |
| Similkameen 1 | $64.3(11.1)$ | $73.7(6.5)$ |
| Similkameen 2 | $64.2(12.5)$ | $72.3(5.9)$ |
| Total | $\mathbf{6 2 . 6}(\mathbf{1 0 . 5})$ | $\mathbf{7 2 . 1}(6.4)$ |

### 8.6 Life History Monitoring

Life history characteristics of Okanogan/Similkameen summer Chinook were assessed by examining carcasses on spawning grounds and fish collected or examined at broodstock collection sites, and by reviewing tagging data and fisheries statistics.

## Migration Timing

Migration timing for Okanogan/Similkameen summer Chinook is described in Section 7.6.

## Age at Maturity

Most of the wild and hatchery summer Chinook sampled during the period 1993-2009 in the Okanogan Basin were age-4 and 5 fish (total age) (Table 8.14; Figure 8.5). A higher percentage of age- 3 and 4 wild Chinook returned to the basin than did age- 3 and 4 hatchery Chinook. In contrast, a higher proportion of age- 5 and 6 hatchery fish returned than did age- 5 and 6 wild fish. Thus, a higher percentage of hatchery fish returned at an older age than did wild fish.

Table 8.14. Proportions of wild and hatchery summer Chinook of different ages (total age) sampled on spawning grounds in the Okanogan Basin, 1993-2009.

| Sample year | Total age | Sample |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  |  |  |

Okan/Similk Summer Chinook

Figure 8.5. Proportions of wild and hatchery summer Chinook of different total ages sampled at broodstock collection sites and on spawning grounds in the Okanogan Basin for the combined years 1993-2009.

## Size at Maturity

On average, hatchery summer Chinook were about 2 cm smaller than wild summer Chinook sampled in the Okanogan Basin (Table 8.15). This is interesting given that a slightly higher percentage of hatchery fish returned as age-5 and 6 fish than did wild fish. Future analyses will compare sizes of hatchery and wild fish of the same age groups and gender.

Table 8.15. Mean lengths ( $\mathrm{POH} ; \mathrm{cm}$ ) and variability statistics for wild and hatchery summer Chinook sampled in the Okanogan Basin, 1993-2009; SD = 1 standard deviation.

## Contribution to Fisheries

Most of the harvest on hatchery-origin Okanogan/Similkameen summer Chinook occurred in the Ocean (Table 8.16). Ocean harvest has made up $38-100 \%$ of all hatchery-origin Okanogan/Similkameen summer Chinook harvested. Brood years 1989, 1997-2000, and 20022004 provided the largest harvests, while brood year 1996 provided the lowest.
Table 8.16. Estimated number and percent (in parentheses) of hatchery-origin Okanogan/Similkameen summer Chinook captured in different fisheries, brood years 1989-2004.

## Straying

Stray rates were determined by examining CWTs recovered on spawning grounds within and outside the Okanogan Basin. Targets for strays based on return year (recovery year) and brood year should be less than $5 \%$.
Rates of hatchery-origin Okanogan summer Chinook straying into basins outside the Okanogan have been very low (Table 8.17). Although a few hatchery-origin Okanogan summer Chinook have strayed into other spawning areas, straying, on average, has been less than 5\%. The Chelan tailrace has received the largest number of Okanogan strays.
Table 8.17. Number and percent of spawning escapements within other non-target basins that consisted of hatchery-origin Okanogan summer Chinook, return years 1994-2007. For example, for return year 2002, $1 \%$ of the summer Chinook spawning escapement in the Entiat Basin consisted of hatchery-origin Okanogan summer Chinook. Percent strays should be less than 5\%.

| Return year | Wenatchee |  | Methow |  | Chelan |  | Entiat |  | Hanford Reach |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |

| 2007 | 0 | 0.0 | 3 | 0.2 | 4 | 2.1 | 0 | 0.0 | 0 | 0.0 |
| Total | 17 | 0.0 | 52 | 0.2 | 115 | 2.6 | 28 | 0.8 | 11 | 0.0 |

On average, less than $1 \%$ of the returns have strayed into non-target spawning areas, falling below the target of $5 \%$ (Table 8.18). Depending on brood year, percent strays into non-target spawning areas have ranged from $0-4.2 \%$. Few ( $<1 \%$ on average) have strayed into non-target hatchery programs.
Table 8.18. Number and percent of hatchery-origin Okanogan summer Chinook that homed to target spawning areas and the target hatchery, and number and percent that strayed to non-target spawning areas and non-target hatchery programs, by brood years 1989-2004. Percent stays should be less than 5\%.

## Genetics

Genetic studies were conducted to investigate relationships among temporally replicated collections of summer Chinook from the Wenatchee River, Methow River, and Okanogan River
in the upper Columbia River basin (Kassler et al. 2100; the entire report is appended as Appendix J). Samples from the Eastbank Hatchery - Wenatchee stock, Eastbank Hatchery Methow/Okanogan (MEOK) stock, and Wells Hatchery were also included in the analysis. Samples of natural and hatchery-origin summer Chinook were analyzed and compared to determine if the supplementation program has affected the genetic structure of these populations. The study also calculated the effective number of breeders for collection locations of natural and hatchery-origin summer Chinook from 1993 and 2008.

In general, population differentiation was not observed among the temporally replicated collection locations. A single collection from the Okanogan River (1993) was the only collection showing statistically significant differences. The effective number of breeders was not statistically different from the early collection in 1993 in comparison to the late collection in 2008. Overall, these analyses revealed a lack of differentiation among the temporal replicates from the same locations and among the collection from different locations, suggesting the populations have been homogenized or that there has been substantial gene flow among populations. Additional comparisons among summer-run and fall-run Chinook populations in the upper Columbia River were conducted to determine if there was any differentiation between Chinook with different run timing. These analyses revealed pairwise $\mathrm{F}_{\text {ST }}$ values that were less than 0.01 for the collections of summer Chinook to collections of fall Chinook from Hanford Reach, lower Yakima River, Priest Rapids, and Umatilla. Collections of fall Chinook from Crab Creek, Lyons Ferry Hatchery, Marion Drain, and Snake River had pairwise $\mathrm{F}_{\text {ST }}$ values that were higher in comparison to the collections of summer Chinook. The consensus clustering analysis did not provide good statistical support to the groupings, but did show relationships among collections based on geographic proximity. Overall the summer and fall run Chinook that have historically been spawned together were not differentiated while fall Chinook from greater geographic distances were differentiated.

## Proportion of Natural Influence

Another method for assessing the genetic risk of a supplementation program is to determine the influence of the hatchery and natural environments on the adaptation of the composite population. This is estimated by the proportion of natural-origin fish in the hatchery broodstock ( pNOB ) and the proportion of hatchery-origin fish in the natural spawning escapement ( pHOS ). The ratio $\mathrm{pNOB} /(\mathrm{pHOS}+\mathrm{pNOB})$ is the Proportion of Natural Influence (PNI). The larger the ratio ( PNI ), the greater the strength of selection in the natural environment relative to that of the hatchery environment. In order for the natural environment to dominate selection, PNI should be greater than 0.5 (HSRG/WDFW/NWIFC 2004).

For brood years 1989-2009, the PNI was equal to or greater than 0.5 in 12 out of the 21 years (Table 8.19). This indicates that in those years the natural environment has had a relatively greater influence on adaptation of Okanogan/Similkameen summer Chinook than has the hatchery environment.

Table 8.19. Proportionate natural influence (PNI) of the Okanogan/Similkameen summer Chinook supplementation program for brood years 1989-2009. PNI was calculated as the proportion of naturally produced Chinook in the hatchery broodstock ( pNOB ) divided by the proportion of hatchery Chinook on the spawning grounds ( pHOS ) plus pNOB. NOS $=$ number of natural-origin Chinook on the spawning grounds; HOS = number of hatchery-origin Chinook on the spawning grounds; $\mathrm{NOB}=$ number of naturalorigin Chinook collected for broodstock; and HOB = number of hatchery-origin Chinook included in hatchery broodstock.

| Brood year | Spawners |  |  | Broodstock |  |  | PNI |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  | NOS | HOS | pHOS | NOB | HOB | pNOB |  |

## Natural and Hatchery Replacement Rates

Natural replacement rates (NRR) were calculated as the ratio of natural-origin recruits (NOR) to the parent spawning population (spawning escapement). For brood years 1989-2003, NRR for summer Chinook in the Okanogan averaged 1.19 (range, 0.16-3.79) if harvested fish were not include in the estimate and 2.47 (range, $0.35-10.17$ ) if harvested fish were included in the estimate (Table 8.20). NRRs for more recent brood years will be calculated as soon as all tag recoveries and sampling rates have been loaded into the database.

Hatchery replacement rates (HRR) are the hatchery adult-to-adult returns and were calculated as the ratio of hatchery-origin recruits (HOR) to the parent broodstock collected. These rates should
be greater than the NRRs and greater than or equal to 5.30 (the calculated target value in Murdoch and Peven 2005). HRRs exceeded NRRs in 12 of the 15 years of data, regardless if harvest was or was not included in the estimate (Table 8.20). Hatchery replacement rates for Okanogan summer Chinook have exceeded the estimated target value of 5.30 in six or nine of the 15 years of data depending on if harvest was or was not included in the estimate.
Table 8.20. Broodstock collected, spawning escapements, natural and hatchery-origin recruits (NOR and HOR), and natural and hatchery replacement rates (NRR and HRR; with and without harvest) for wild summer Chinook in the Okanogan Basin, brood years 1989-2003.

| Brood year | Broodstock Collected | Spawning Escapement | Harvest not included |  |  |  | Harvest included |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  |  |  | HOR | NOR | HRR | NRR | HOR | NOR | HRR | NRR |
| 1989 | 304 | 1,719 | 4,493 | 2,139 | 14.78 | 1.24 | 7,467 | 3,565 | 24.56 | 2.07 |
| 1990 | 288 | 837 | 1,021 | 1,477 | 3.55 | 1.76 | 1,416 | 2,057 | 4.92 | 2.46 |
| 1991 | 364 | 574 | 1,578 | 883 | 4.34 | 1.54 | 1,839 | 1,024 | 5.05 | 1.78 |
| 1992 | 304 | 473 | 1,845 | 1,069 | 6.07 | 2.26 | 2,324 | 1,350 | 7.64 | 2.85 |
| 1993 | 328 | 1,485 | 87 | 474 | 0.27 | 0.32 | 117 | 637 | 0.36 | 0.43 |
| 1994 | 302 | 4,033 | 1,144 | 1,397 | 3.79 | 0.35 | 1,561 | 1,911 | 5.17 | 0.47 |
| 1995 | 385 | 3,002 | 2,204 | 1,357 | 5.72 | 0.45 | 2,906 | 1,795 | 7.55 | 0.60 |
| 1996 | 330 | 1,819 | 27 | 730 | 0.08 | 0.40 | 32 | 870 | 0.10 | 0.48 |
| 1997 | 313 | 2,189 | 12,005 | 4,418 | 38.35 | 2.02 | 19,251 | 7,103 | 61.50 | 3.24 |
| 1998 | 352 | 1,092 | 2,919 | 4,144 | 8.29 | 3.79 | 7,793 | 11,110 | 22.14 | 10.17 |
| 1999 | 333 | 3,617 | 856 | 6,679 | 2.57 | 1.85 | 2,850 | 22,338 | 8.56 | 6.18 |
| 2000 | 334 | 3,701 | 2,229 | 1,729 | 6.67 | 0.47 | 6,775 | 5,271 | 20.28 | 1.42 |
| 2001 | 335 | 10,857 | 107 | 8,994 | 0.32 | 0.83 | 426 | 35,976 | 1.27 | 3.31 |

| 2003 | 337 | 3,420 | 1,638 | 558 | 4.86 | 0.16 | 3,479 | 1,187 | 10.32 | 0.35 |
| Average | 329 | 3,512 | 2,192 | 2,806 | 6.79 | 1.19 | 4,013 | 7,496 | 12.35 | 2.47 |

## Smolt-to-Adult Survivals

Smolt-to-adult survival ratios (SARs) were calculated as the number of hatchery adult recaptures divided by the number of tagged hatchery smolts released. SARs were based on CWT returns. For the available brood years, SARs have ranged from 0.00006 to 0.03272 for hatchery summer Chinook in the Okanogan Basin (Table 8.21).

Table 8.21. Smolt-to-adult ratios (SARs) for Okanogan/Similkameen summer Chinook, brood years 1989-2004.

| Brood year | Number of tagged smolts $_{\text {released }^{\mathbf{a}}}$ | Estimated adult captures $^{\mathbf{b}}$ | SAR |
| :---: | :---: | :---: | :---: |
| 1989 | 202,125 | 4,298 | 0.02126 |
| 1990 | 367,207 | 969 | 0.00264 |
| 1991 | 360,380 | 977 | 0.00271 |
| 1992 | 537,190 | 2,299 | 0.00428 |

| Brood year | Number of tagged smolts released ${ }^{\text {a }}$ | Estimated adult captures ${ }^{\text {b }}$ | SAR |
| :---: | :---: | :---: | :---: |
| 1993 | 379,139 | 117 | 0.00031 |
| 1994 | 217,818 | 1,538 | 0.00706 |
| 1995 | 574,197 | 2,855 | 0.00497 |
| 1996 | 487,776 | 31 | 0.00006 |
| 1997 | 572,531 | 18,731 | 0.03272 |
| 1998 | 287,948 | 7,684 | 0.02669 |
| 1999 | 610,868 | 2,779 | 0.00455 |
| 2000 | 528,639 | 6,748 | 0.01276 |
| 2001 | 26,315 | 424 | 0.01611 |
| 2002 | 245,997 | 1,953 | 0.00794 |
| 2003 | 574,908 | 3,464 | 0.00603 |
| 2004 | 579,570 | 10,730 | 0.01851 |
| Average | 409,538 | 4,100 | 0.01001 |

${ }^{\text {a }}$ Includes all tag codes and CWT released fish (CWT + Ad Clip fish and CWT-only fish).
${ }^{\mathrm{b}}$ Includes estimated recoveries (spawning ground, hatcheries, harvest, etc.) and observed recoveries if estimated recoveries were unavailable.

### 8.7 ESA/HCP Compliance

## Broodstock Collection

Because summer Chinook adults collected at Wells Dam are used for both the Methow and Okanogan supplementation programs, please refer to Section 7.7 for information on ESA compliance during broodstock collection.

## Hatchery Rearing and Release

The 2008 brood Okanogan/Similkameen summer Chinook reared throughout their juvenile lifestages at Eastbank Fish Hatchery and Similkameen and Bonaparte Acclimation ponds without significant incident; although, there was some elevated mortality associated with bacterial coldwater disease and bacterial gill disease (see Section 8.3). The 2008 brood smolt release from the Similkameen and Bonaparte ponds totaled 519,357 summer Chinook, representing $90.8 \%$ of the production objective for the Okanogan/Similkameen program and was compliant with the $10 \%$ overage in production allowable in ESA Section 10 Permit 1347.

## Hatchery Effluent Monitoring

Per ESA Permits 1196, 1347, and 1395, permit holders shall monitor and report hatchery effluents in compliance with applicable National Pollution Discharge Elimination Systems (NPDES) (EPA 1999) permit limitations. There were no NPDES violations reported at Chelan PUD Hatchery facilities during the period 1 January 2010 through 31 December 2010. NPDES monitoring and reporting for Chelan PUD Hatchery Programs during 2010 are provided in Appendix E.

## Spawning Surveys

Summer Chinook spawning ground surveys conducted in the Okanogan Basin during 2010 were consistent with ESA Section 10 Permit No. 1347. Because of the difficulty of quantifying the level of take associated with spawning ground surveys, the Permit does not specify a take level associated with these activities, even though it does authorize implementation of spawning ground surveys. Therefore, no take levels are reported. However, to minimize potential impacts to established redds, wading was restricted to the extent practical, and extreme caution was used to avoid established redds when wading was required.

## SECTION 9: TURTLE ROCK SUMMER CHINOOK

### 9.1 Broodstock Sampling

Broodstock for the Turtle Rock programs (yearling and sub-yearling) are collected as part of the Wells summer Chinook volunteer program. Refer to Snow et al. (2007) for information related to adults collected for these programs.

### 9.2 Hatchery Rearing

## Rearing History

## Number of eggs taken

Broodstock for the Turtle Rock summer Chinook are collected at Wells Dam and consist of volunteers to the hatchery. In recent years some naturally produced fish have been incorporated into the brood. Eyed eggs are transferred from Wells FH to Eastbank FH for rearing. As such, the number of green (unfertilized) eggs collected for this program is reported as egg inventory and distribution reports provided by Wells FH personnel.

## Disease

Within the normal and accelerated subyearling program, the primary cause of mortality in the early life stages (swim-up to early ponding) continues to be coagulated yolk as a result of lack of chilled water during incubation. No additional significant health concerns were encountered with the two subyearling groups during rearing and no treatments were recommended. External fungus was diagnosed in the yearling program in December. No further issue developed after treatment. No additional disease-related problems were noted before the fish were released.

## Number of acclimation days

Rearing of the 2008-brood normal and accelerated subyearling Turtle Rock summer Chinook was similar to previous years with fish being held on well water before being transferred to Turtle Rock for final acclimation on 11 May 2009. Both rearing groups were released on 11 June 2009 after 32 days of acclimation on Columbia River water. One group of yearling Turtle Rock summer Chinook was released on 7 May 2010, after 180 days of acclimation on Columbia River water. The Chelan River net pen group was released on 29 April, after 165 days of acclimation on Chelan River water.

## Release Information

## Numbers released

The 2009 subyearling Turtle Rock summer Chinook program achieved $88.0 \%$ of the 810,000 target goal with about 713,130 fish being released (Table 9.1). The accelerated subyearling summer Chinook program was discontinued; however, releases of accelerated subyearling Chinook in past years are shown in Table 9.2. It is important to note that the subyearling program has been terminated. Production (400,000 fish) from the subyearling programs was converted to the yearling program.

The 2008 yearling summer Chinook program achieved $75.6 \%$ of the 600,000 target goal with about 453,761 fish being released (252,762 from Turtle Rock and 200,999 from the Chelan River net pens) (Table 9.3). Releases of 2009 yearling Chinook will be reported in the 2011 report.
Table 9.1. Numbers of Turtle Rock summer Chinook subyearlings released from the hatchery, 19952010. The release target for Turtle Rock summer Chinook subyearlings is 810,000 fish.

## Numbers tagged

About $53.0 \%$ of the 2008 Turtle Rock accelerated subyearling Chinook and $63.6 \%$ of the normal subyearling Chinook were adipose fin-clipped and CWT. The remaining fish were released untagged and unmarked. The 2008 yearling Chinook were $98.2 \%$ CWT and adipose fin-clipped.
In 2010, a total of 10,101 summer Chinook from the 2009 brood were PIT tagged at Ringold Fish Hatchery during 24-25 and 25-26 August. Fish were tagged in two groups of about 5,050 per group. One group consisted of Turtle Rock Hatchery fish and the other Chelan River Net Pens fish. Fish were not fed during tagging or for 1-2 days before and after tagging. Chinook from the Turtle Rock group averaged 88 mm in length and 7.6 g at time of tagging. Those from the Chelan Net Pens group averaged 82 mm in length and 6.6 g . As of the end of January 2011,

101 tagged Chinook have died (100 from the Turtle Rock group and one from the Chelan Net Pens group). No fish have shed their tags. This leaves 10,000 tagged summer Chinook alive at the end of the month.

Table 9.4 summarizes the number of yearling summer Chinook that have been PIT-tagged and released from the Turtle Rock Program.

Table 9.4. Summary of PIT-tagging activities for Turtle Rock yearling summer Chinook, brood years 2007-2009.

## Fish size and condition at release

Size at release of the 2008 normal subyearling Turtle Rock summer Chinook was $76.8 \%$ and $69.3 \%$ of the target fork length and weight, respectively. This brood year was below the target CV for length by $12 \%$ (Table 9.5).
Table 9.5. Mean lengths (FL, mm), weight (g and fish/pound), and coefficient of variation (CV) of Turtle Rock summer Chinook subyearlings released from the hatchery, 1995-2008. Size targets are provided in the last row of the table.

| Brood year | Release year | Fork length (mm) |  | Mean weight |  |
| :---: | :---: | :---: | :---: | :---: | :---: |
|  |  | Mean | CV | Grams (g) | Fish/pound |
| 1995 | 1996 | 102 | 6.3 | 12.6 | 36 |

## Survival Estimates

## Normal subyearling releases

Overall survival of the normal subyearling Turtle Rock summer Chinook program from green egg to release was below the standard set for the program (Table 9.8). Lower than expected survival at ponding and post-ponding reduced the overall program performance.
Table 9.8. Hatchery life-stage survival rates (\%) for Turtle Rock subyearling (zero program) summer Chinook, brood years 2004-2008. Survival standards or targets are provided in the last row of the table.

## Yearling releases

Overall survival of the yearling Turtle Rock summer Chinook program from green egg to release was above the standard set for the program (Table 9.10). Higher than expected survivals in all life stages contributed to the increased program performance.
Table 9.10. Hatchery life-stage survival rates (\%) for Turtle Rock yearling summer Chinook, brood years 2004-2008. Survival standards or targets are provided in the last row of the table.

### 9.3 Life History Monitoring

Life history characteristics of Turtle Rock summer Chinook were assessed by examining carcasses on spawning grounds and by reviewing tagging data and fisheries statistics.

## Contribution to Fisheries

## Normal subyearling releases

Most of the harvest on Turtle Rock summer Chinook (normal subyearling releases) occurred in the Ocean (10-100\% of the fish harvested; Table 9.11). Brood year 1995, 1999, and 2001 provided the largest total harvests, while brood year 1997 and 2003 provided the lowest.

Table 9.11. Estimated number and percent (in parentheses) of Turtle Rock summer Chinook (normal subyearling releases) captured in different fisheries, brood years 1995-2004.

| Brood year | Ocean fisheries | Columbia River Fisheries |  |  | Total |
| :---: | :---: | :---: | :---: | :---: | :---: |
|  |  | Tribal | Commercial <br> (Zones 1-5) | Recreational <br> (sport) |  |
| 1995 | $693(84)$ | $106(13)$ | $11(1)$ | $16(2)$ | 826 |

## Accelerated subyearling releases

Most of the harvest on Turtle Rock summer Chinook (accelerated subyearling releases) occurred in ocean fisheries (Table 9.12). Ocean harvest has made up $27 \%$ to $100 \%$ of all Turtle Rock summer Chinook harvested (no fish from the 2003 brood year were harvested). Brood year 1999 provided the largest total harvest, while brood years 1995, 1997, 2002, and 2003 provided the lowest.

Table 9.12. Estimated number and percent (in parentheses) of Turtle Rock summer Chinook (accelerated subyearling releases) captured in different fisheries, brood years 1995-2004.

| Brood year | Ocean fisheries | Columbia River Fisheries |  |  | Total |
| :---: | :---: | :---: | :---: | :---: | :---: |
|  |  | Tribal | Commercial <br> (Zones 1-5) | Recreational <br> (sport) |  |

## Yearling releases

Most of the harvest on Turtle Rock summer Chinook (yearling releases) occurred in ocean fisheries (Table 9.13). Ocean harvest has made up $43 \%$ to $95 \%$ of all Turtle Rock summer

Chinook harvested. Brood year 1998 provided the largest harvest, while brood year 1995 provided the lowest.

Table 9.13. Estimated number and percent (in parentheses) of Turtle Rock summer Chinook (yearling releases) captured in different fisheries, brood years 1995-2004.

| Brood year | Ocean fisheries | Columbia River Fisheries |  |  | Total |
| :---: | :---: | :---: | :---: | :---: | :---: |

## Straying

## Normal subyearling releases

Rates of Turtle Rock summer Chinook (normal subyearling releases) straying into spawning areas in the upper basin have been low (Table 9.14). Although a few Turtle Rock summer Chinook have strayed into other spawning areas, straying, on average, has been less than $5 \%$. The Chelan tailrace has received the largest number of Turtle Rock strays.

Table 9.14. Number (No.) and percent of spawning escapements within other non-target basins that consisted of Turtle Rock summer Chinook (normal subyearling releases), return years 1998-2007. For example, for return year 2003, $0.6 \%$ of the summer Chinook spawning escapement in the Okanogan Basin consisted of Turtle Rock summer Chinook. Percent strays should be less than 5\%.

| Return year | Wenatchee |  | Methow |  | Okanogan |  | Chelan |  | Entiat |  | Hanford Reach |  |

## Yearling releases

Rates of Turtle Rock summer Chinook (yearling releases) straying into spawning areas in the upper basin have varied widely depending on spawning area (Table 9.18). Most of these fish strayed to spawning areas within the Chelan tailrace, Entiat Basin, and Methow Basin. Relatively few, on average, have strayed to spawning areas in the Okanogan Basin, Wenatchee Basin, and the Hanford Reach.

Table 9.18. Number (No.) and percent of spawning escapements within other non-target basins that consisted of Turtle Rock summer Chinook (yearling releases), return years 1998-2007. For example, for return year 2003, $4.3 \%$ of the summer Chinook spawning escapement in the Methow Basin consisted of Turtle Rock summer Chinook. Percent strays should be less than 5\%.

## Smolt-to-Adult Survivals

Subyearling-to-adult and smolt-to-adult survival ratios (SARs) were calculated as the number of hatchery adult recaptures divided by the number of tagged hatchery subyearling or yearling Chinook released. SARs were based on CWT returns.

## Normal subyearling releases

For the available brood years, SARs for normal subyearling-released Chinook have ranged from 0.000034 to 0.001562 (Table 9.20).

Table 9.20. Subyearling-to-adult ratios (SARs) for Turtle Rock normal subyearling-released summer Chinook, brood years 1995-2004.

| Brood year | Number released $^{\text {a }}$ | Estimated adult captures $^{\mathbf{b}}$ | SAR |
| :---: | :---: | :---: | :---: |
| 1995 | 201,230 | 205 | 0.001019 |

| Average | $\mathbf{1 9 1 , 9 8 1}$ | $\mathbf{1 4 5}$ | $\mathbf{0 . 0 0 0 7 5 4}$ |

${ }^{\text {a }}$ Includes all tag codes and CWT released fish (CWT + Ad Clip fish and CWT-only fish).
${ }^{\mathrm{b}}$ Includes estimated recoveries (spawning ground, hatcheries, harvest, etc.) and observed recoveries if estimated recoveries were unavailable.

## Yearling releases

For the available brood years, SARs for yearling-released Chinook have ranged from 0.007184 to 0.026799 (Table 9.22).

Table 9.22. Smolt-to-adult ratios (SARs) for Turtle Rock yearling-released summer Chinook, brood years 1995-2004.

| Brood year | Number released $^{\mathbf{a}}$ | Estimated adult captures $^{\mathbf{b}}$ | SAR |
| :---: | :---: | :---: | :---: |
| 1995 | 145,318 | 1,044 | 0.007184 |
| 1996 | 194,251 | 1,557 | 0.008015 |
| 1997 | 198,924 | 4,814 | 0.024200 |
| 1998 | 215,646 | 5,779 | 0.026799 |
| 1999 | 280,683 | 2,673 | 0.009523 |
| 2000 | 165,072 | 1,868 | 0.011316 |
| 2001 | 199,694 | 3,884 | 0.019450 |
| 2002 | 192,234 | 2,525 | 0.013135 |
| 2003 | 199,386 | 2,045 | 0.010256 |
| 2004 | 202,682 | 2,404 | 0.011861 |
| Average | $\mathbf{1 9 9 , 3 8 9}$ | $\mathbf{2 , 8 5 9}$ | $\mathbf{0 . 0 1 4 3 4 0}$ |

${ }^{\text {a }}$ Includes all tag codes and CWT released fish (CWT + Ad Clip fish and CWT-only fish).
${ }^{\mathrm{b}}$ Includes estimated recoveries (spawning ground, hatcheries, harvest, etc.) and observed recoveries if estimated recoveries were unavailable.

### 9.4 ESA/HCP Compliance

## Broodstock Collection

The 2008 brood Turtle Rock summer Chinook program is supported through adult collections at the volunteer trap at Wells Fish Hatchery and in conjunction with the Wells summer Chinook collections. During 2008, broodstock collections at the volunteer trap were consistent with the 2008 Upper Columbia River Salmon and Steelhead Broodstock Objectives and site-based broodstock collection protocols as required in ESA permit 1347. The 2008 collection totaled 1,388 summer Chinook (combined Wells Fish Hatchery and Turtle Rock Fish Hatchery programs), representing $99.6 \%$ of the targeted 1,393 broodstock collection objective. The minor difference in adult broodstock was a result of enumeration errors during collection.

## Hatchery Rearing and Release

Brood year 2008 releases totaled 1,135,084 fish, including yearling, regular subyearling, and accelerated subyearling releases ( $453,761,309,003$, and 372,320 juveniles, respectively). These releases represented $62.3 \%$ of the Rocky Reach HCP and ESA Section 10 Permit 1347 production for the combined Turtle Rock yearling and subyearling production.

Consistent with ESA Permit 1347, a total of 393,856 normal and accelerated subyearling Chinook were adipose fin clipped and coded-wire tagged, representing $98.5 \%$ of the 400,000 adipose clipped and CWT target for sub-yearling production. The remainder of the subyearling production was released untagged and unmarked. The yearling Chinook were $98.2 \%$ CWT and adipose fin-clipped. About 22,1672008 brood Turtle Rock yearling summer Chinook were PIT tagged. See Section 9.2 for specific rearing, tagging, and release information related to the 2008 brood Turtle Rock summer Chinook program.

## Hatchery Effluent Monitoring

Per ESA Permits 1196, 1347, and 1395, permit holders shall monitor and report hatchery effluents in compliance with applicable National Pollution Discharge Elimination Systems (NPDES) (EPA 1999) permit limitations. There were no NPDES violations reported at Chelan PUD Hatchery facilities during the period 1 January 2010 through 31 December 2010. NPDES monitoring and reporting for Chelan PUD Hatchery Programs during 2010 are provided in Appendix E.

## APPENDIX A

Abundance and Total Numbers of Chinook Salmon and Trout in the Chiwawa River Basin, Washington, 2010.

January 25, 2011

TO: HCP Hatchery Committee
FROM: Tracy Hillman
Subject: Abundance and Total Numbers of Chinook Salmon and Trout in the Chiwawa River Basin, Washington, 2010

The Chelan County Public Utility District (PUD) hatchery program is operated through a habitat conservation program (HCP) that was incorporated into the PUD's license in 2004. The HCP directed the signatories to develop a monitoring and evaluation plan within one year of the effective date. This resulted in the development of the Conceptual Approach to Monitoring and Evaluating the Chelan County Public Utility District Hatchery Programs (Murdoch and Peven 2005). This study will help the HCP Hatchery Committee determine if it is meeting Objective 7 in the monitoring and evaluation plan (Murdoch and Peven 2005).
Objective 7: Determine if the proportion of hatchery fish on the spawning grounds affects the freshwater productivity (i.e., number of juveniles per redd) of supplemented streams when compared to non-supplemented streams.
We estimated densities and total numbers of age-0 spring Chinook salmon Oncorhynchus tshawytscha, trout Oncorhynchus sp., and char Salvelinus sp. in the Chiwawa River Basin, Washington, in August 2010. This was the $18^{\text {th }}$ year of an ongoing study to assess the freshwater productivity (juveniles/redd) of Chinook salmon in the Chiwawa Basin. We used landscape classification to stratify streams in the basin that supported juvenile Chinook salmon (Hillman and Miller 2004). Classification "explained" most of the variability in fish numbers caused by geology, land type, valley bottom type, stream state condition, and habitat type. We identified ten reaches on the lower 31 miles ( 50 km ) of the Chiwawa River and one reach in each of Phelps, Rock, Chikamin, Big Meadow, Alder, Brush, Clear, Y, and Unnamed ${ }^{1}$ creeks (Figure 1). Each reach consisted of several combinations of state-type and habitat-type strata. We used classification to find reference areas for reaches in the Chiwawa River. We matched Reach 3 and Reach 8 of the Chiwawa River with a moderately-confined section of Nason Creek (RM 0.621.70 ) and an unconfined area of the Little Wenatchee River (RM 4.39-8.55), respectively

[^3](Hillman and Miller 2004). Following methods described in Hillman and Miller (2004), we used underwater observations to estimate numbers of fish in 189 randomly selected sites.

During sampling in August 2010, discharge in the Chiwawa River averaged 333 cubic feet per second (cfs) and ranged from 182 to 641 cfs (Figure 2). Stream temperatures for the study period ranged from 9.0 to $18.5^{\circ} \mathrm{C}$. Fish species observed in the Chiwawa Basin and reference areas during the 1992-2010 survey period ${ }^{2}$ included: spring Chinook salmon, coho salmon O. kisutch, sockeye salmon O. nerka (in the Little Wenatchee River reference area), steelhead/rainbow trout O. mykiss (hatchery rainbow were present only in 1992 and 1993), cutthroat trout O. clarki lewisi, bull trout $S$. confluentus, brook trout $S$. fontinalis, mountain whitefish Prosopium williamsoni, dace Rhinichthys sp., suckers Catostomus sp., and sculpin Cottus sp. The age-0 spring Chinook that we observed in the Chiwawa Basin during the 2010 survey were produced from 421 redds counted in the fall of 2009 (Hillman et al. 2010). Assuming a mean fecundity of 4,573 eggs per female Chinook (from females collected for broodstock), and that no female produced more than one redd (Murdoch et al. 2009), we estimated that the Chiwawa River Basin was seeded with 1,925,233 eggs in 2009 (Appendix A).

In 2010, riffles made up the largest fraction of habitat types in reaches of the Chiwawa Basin (53\% of the total stream surface area) (Table 1). Pools (23\%), glides (8\%), and multiple channels $(16 \%)$ constituted the remaining $47 \%$ of the stream surface area. We consistently found woody debris associated with multiple-channel habitat.

## Chinook Salmon Abundance

Chinook salmon were the most abundant salmonid in the Chiwawa Basin. We estimated, based on surface area, that age-0 Chinook salmon numbered $128,220( \pm 14 \%$ of the estimated total) in the Chiwawa River Basin in August 2010 (Table 2). Extrapolating based on volume of habitat types, age-0 Chinook numbered $132,526( \pm 26 \%)$ in the Chiwawa Basin. About $8 \%$ of the juvenile Chinook were in tributaries to the Chiwawa River. During the 1992-2010 surveys, numbers of age-0 Chinook ranged from 5,815 to 134,874 in the Chiwawa Basin (Figure 3; Appendix B). Most of the difference in juvenile numbers among years resulted from different seeding levels (Figure 4). Numbers of Chinook redds in the Chiwawa Basin during 1992-2010 ranged from 13 to 1,046 , resulting in seeding levels of 66,248 to $4,836,704$ eggs (Appendix A).
As in most years, age- 0 Chinook in 2010 were distributed contagiously among reaches in the Chiwawa River (Table 2). In the Chiwawa River, densities of age-0 Chinook were highest in the upper reaches (Reaches 7-10). The highest densities in the Chiwawa Basin were in tributaries to the Chiwawa River (Table 2). Age-0 Chinook were most abundant in multiple channels and least abundant in glides and riffles. We found the majority of the Chinook associated with woody debris in multiple channels (multiple channel use index $=2.82)^{3}$. These sites (multiple channels)

[^4]made up $16 \%$ of the total area of the Chiwawa Basin, but they provided habitat for $53 \%$ of all the age-0 Chinook in the basin in 2010 (Appendix C). In contrast, riffles made up 53\% of the total area, but provided habitat for only $11 \%$ of all age-0 Chinook in the Chiwawa Basin (riffle use index $=0.25$ ). Pools made up $23 \%$ of the total area and provided habitat for $34 \%$ of all age- 0 Chinook in the basin (pool use index $=1.50$ ). Few Chinook used glides that lacked woody debris (glide use index $=0.26$ ).

As noted earlier, we assumed that the Chiwawa River was seeded with 1,925,233 Chinook eggs (421 redds times 4,573 eggs/female) in fall, 2009, and that at least 128,220 of those survived to August 2010. This means that the egg-to-parr survival was at least $6.7 \%$ ( $95 \%$ confidence bound 5.7-7.6\%). During 1992-2010, egg-to-parr survival averaged $9.0 \%$ (range 2.7-19.1\%) in the Chiwawa Basin (Appendix A). This survival rate comports with those from other streams. For example, Mullan et al. (1992) estimated an egg-to-parr survival rate of $9.8 \%$ for spring Chinook salmon in Icicle Creek, a tributary of the Wenatchee River. Using a Beverton and Holt model, Hubble (1993) estimated that egg-to-parr survival of Chinook in the Chewuck River, a tributary to the Methow River, ranged between $13 \%$ and $32 \%$, depending on percent seeding level in the basin. Kiefer and Forster (1991) estimated a mean egg-to-parr survival rate of 5.5\% (range 5.1$6.7 \%$ ) for naturally-spawning spring Chinook salmon in the entire upper Salmon River. They also noted that egg-to-parr survival of natural spawners and adult outplants in the headwater streams of the upper Salmon River averaged 24.4\% (range 16.1-32.0\%). Petrosky (1990) reported an egg-to-parr survival range of 1.2-29.0\% for Chinook in the upper Salmon River, Idaho. Konopacky et al. (1986) estimated egg-to-parr survival of Chinook in Bear Valley Creek, Idaho, as 8.1-9.4\%. Work by Richards and Cernera (1987) in Bear Valley Creek indicated an egg-to-parr survival of $2.1 \%$.
Mean densities of age- 0 Chinook salmon in two reaches of the Chiwawa River were generally less than those in corresponding reference areas (Figure 5). Within both the Chiwawa River and its reference areas, pools and multiple channels consistently had the highest densities of age-0 Chinook.

We estimated a total of $291( \pm 31 \%$ of the estimated total) age- $1+$ Chinook salmon in the Chiwawa Basin in August 2010 (Table 3). In August 1992-2010, numbers of age-1+ Chinook ranged from 5 to 563 in the Chiwawa River Basin (Figure 3; Appendix B). These fish occurred throughout the Chiwawa River. We found relatively few age-1+ Chinook in tributaries. Age-1+ Chinook were most abundant in multiple channels and pools.

## Juvenile Chinook Salmon Productivity (Fish/Redd)

Freshwater productivity of juvenile Chinook salmon was estimated as the number of parr (age-0 Chinook) per redd in the Chiwawa Basin. Theoretically, the relationship between number of parr and redds can be explained mathematically provided the relationship between the two parameters goes through the origin, increases monotonically at low spawning levels, and shows some level of density dependence at high spawning levels. We identified five alternative hypotheses that may explain the relationship between spawning level (redds) and numbers of age-0 Chinook:
use of multiple channels to a greater extent than the average, while scores between 0 and 1 indicate below-average use of multiple channel habitat.

1. The first hypothesis assumed that because of low spawner escapements, the number of juvenile Chinook increases linearly with increasing numbers of redds. This hypothesis assumes that there is no density dependence because of low seeding levels. This hypothesis was modeled with a density-independent function that took the form:

$$
J=\alpha R
$$

where $\boldsymbol{J}$ is the number of juvenile (age-0) Chinook, $\boldsymbol{R}$ is the number or redds, and $\boldsymbol{\alpha}$ is the increase in numbers of juveniles with each incremental increase in redds.
2. The second hypothesis assumed that the number of juveniles increases constantly toward an asymptote as the number of redds increases. After the asymptote is reached, the number of juveniles neither increases nor decreases. The asymptote represents the maximum number of juveniles the system can support (i.e., carrying capacity for the system). This hypothesis was modeled with a Beverton-Holt curve that took the form:

$$
J=\frac{(\alpha R)}{(\beta+R)}
$$

where $\boldsymbol{J}$ and $\boldsymbol{R}$ are as above, $\boldsymbol{\alpha}$ is the maximum number of juveniles produced, and $\boldsymbol{\beta}$ is the number of redds needed to produce (on average) juveniles equal to one-half the maximum number of juveniles.
3. The third hypothesis, like the second, assumed that the number of juveniles increases toward an asymptote (carrying capacity) as the number of redds increases. After the carrying capacity is reached, the number of juveniles neither increases nor decreases. The carrying capacity represents the maximum number of juveniles the system can support. This hypothesis was modeled with a smooth hockey stick function that took the form:

$$
J=J_{\infty}\left(1-e^{-\left(\frac{\alpha}{J \infty}\right) R}\right)
$$

where $\boldsymbol{J}$ and $\boldsymbol{R}$ are as above, $\boldsymbol{\alpha}$ is the slope at the origin of the spawner-recruitment curve, and $J_{\infty}$ is the carrying capacity of juveniles.
4. The fourth hypothesis assumed that the number of juveniles increases to a maximum and then declines as the number or redds increases. In this case, mortality rate of juveniles (or eggs) is proportional to the initial number of redds. Higher mortality rate is associated with density-dependent growth coupled with size-dependent predation. This hypothesis was modeled with a Ricker curve that took the form:

$$
J=\alpha R e^{-\beta R}
$$

where $\boldsymbol{J}$ and $\boldsymbol{R}$ are as above, $\boldsymbol{\alpha}$ is the number of juveniles per redd at low spawning levels, and $\boldsymbol{\beta}$ describes how quickly the juveniles per redd drop as the number of redds increases.
5. The fifth hypothesis, like the second, assumed that the number of juveniles increases constantly, but unlike the second, the number of juveniles does not reach an asymptote. Rather, the number of juveniles increases indefinitely, but at a slowing rate of increase. This hypothesis was modeled with both a Cushing curve and a Gamma function. The

Cushing curve took the form:

$$
\boldsymbol{J}=\boldsymbol{\alpha} \boldsymbol{R}^{\gamma}
$$

where $\boldsymbol{J}$ and $\boldsymbol{R}$ are as above, $\boldsymbol{\alpha}$ is the number of juveniles per redd at low spawning levels, and $\gamma$ describes the level of density dependence at high spawning levels. The Gamma function is a three-parameter model that has the form:

$$
J=\alpha R^{\gamma} e^{-\beta R}
$$

This is an un-normalized gamma function that is similar to the Cushing curve when $\beta=0$.
We used Akaike's Information Criterion for small sample size ( $\mathrm{AIC}_{\mathrm{c}}$ ) to determine which model(s) best explained the productivity of juvenile Chinook in the Chiwawa Basin. AIC ${ }_{c}$ was estimated as:

$$
A I C_{\mathrm{c}}=-2 \log (£(\theta \mid \text { data }))+2 K+\left(\frac{2 K(K+1)}{n-K-1}\right)
$$

where $\boldsymbol{\operatorname { l o g }}(\boldsymbol{f}(\boldsymbol{\theta} \mid$ data $))$ is the maximum likelihood estimate, $\boldsymbol{K}$ is the number of estimable parameters (structural parameters plus the residual variance parameter), and $\boldsymbol{n}$ is the sample size (Burnham and Anderson 2002). We used least-squares methods to estimate $\boldsymbol{\operatorname { l o g }}(\boldsymbol{£}(\boldsymbol{\theta} \mid \boldsymbol{d a t a})$ ), which was calculated as $\boldsymbol{\operatorname { l o g }}\left(\sigma^{2}\right)$, where $\sigma^{2}=$ residual sum of squares divided by the sample size ( $\sigma^{2}=\boldsymbol{R S S} / \boldsymbol{n}$ ). AIC $\mathrm{c}_{\mathrm{c}}$ assesses model fit in relation to model complexity (number of parameters). The model with the smallest $\mathrm{AIC}_{\mathrm{c}}$ value represents the "best approximating" model within the model set. Remaining models were ranked relative to the best model using $\mathrm{AIC}_{\mathrm{c}}$ difference scores $(\boldsymbol{\Delta} \mathbf{A I C} \mathbf{c})$, Akaike weights ( $\left.\boldsymbol{w}_{\boldsymbol{i}}\right)$, and evidence ratios. Models with $\boldsymbol{\Delta} \mathbf{A I C} \mathbf{C}_{\mathbf{c}}$ values less than 2 indicate that there is substantial support for these models as being the best-fitting models within the set (Burnham and Anderson 2002). Models with values greater than 2 have less support. Akaike weights are probabilities estimating the strength of the evidence supporting a particular model as being the best model within the model set. Models with small $\boldsymbol{w}_{i}$ values are less plausible as competing models (Burnham and Anderson 2002). If no single model could be specified as the best model, a "best subset" of competing models was identified using (1) AIC ${ }_{c}$ differences to indicate the level of empirical support each model had as being the best model, (2) evidence ratios based on Akaike weights to indicate the relative probability that any model is the best model, and (3) coefficients of determination $\left(R^{2}\right)$ assessing the explanatory power of each model.

The use of $\mathrm{AIC}_{\mathrm{c}}$ indicated that the Beverton-Holt model best approximated the information in the juveniles/redd data (Table 4; Figure 6). The estimated structural parameters for this model were:

$$
\text { Juveniles }=\frac{(133,561 \times \text { Redds })}{(158+\text { Redds })}
$$

where the estimated standard errors of the two parameters were 24,529 and 81,561 , respectively. The adjusted $R^{2}=0.81$. The second-best model was the Ricker model, which was $5.99 \mathrm{AIC}_{\mathrm{c}}$ units from the best model (Table 4; Figure 6). The estimated parameters for this model were:

$$
\text { Juveniles }=603 \times \text { Redds } \times e^{-(0.00187 \times \text { Redds })}
$$

where the estimated standard errors of the two parameters were 77 and 0.00035 , respectively, and the $R^{2}=0.73$. The $\mathrm{AIC}_{\mathrm{c}}$ difference scores, Akaike weights, and evidence ratios indicated that there was substantial support for the Beverton-Holt model (Table 4). There was less support for the remaining models (Ricker, Gamma ${ }^{4}$, Cushing, smooth hockey stick, and Density Independent), which were $>4 \mathrm{AIC}_{\mathrm{c}}$ units from the best model. This was further supported by the fact that, relative to the best model, the remaining models had evidence ratios greater than 6.
Although the Beverton-Holt, Ricker, and smooth hockey stick models have different biological assumptions, they all indicated a density-dependent relationship between spawning levels (redds) and juvenile Chinook production. This was not only evident in the best approximating model, but there was also a significant negative relationship between juveniles per redd and numbers of redds in the Chiwawa Basin (Figure 7). Although data at high seeding levels are lacking, the Beverton-Holt model would limit the production of juvenile Chinook to less than about 250,000 parr in the basin (upper 95\% CI of $\boldsymbol{\alpha}$ in the Beverton-Holt model). In contrast, the smooth hockey stick model, which did not fit the data as well as the Beverton-Holt model, would limit the carrying capacity for juvenile Chinook to about 210,000 parr (upper $95 \%$ CI of $\boldsymbol{J}_{\infty}$ in the smooth hockey stick model). Additional information at high spawning escapements is needed to determine more precisely the maximum juvenile productivity in the Chiwawa Basin.

## Steelhead/Rainbow Abundance

Based on stream surface area, we estimated a total of 25,018 ( $\pm 15 \%$ of the estimated total) age-0 steelhead/rainbow ( $<4 \mathrm{in}$ ) in reaches of the Chiwawa Basin in August 2010 (Table 5). During the 1992-2010 survey period, numbers of age-0 steelhead/rainbow ranged from 1,410 to 45,727 in the Chiwawa River Basin (Figure 8; Appendix B). In 1992-2010, numbers of age-0 steelhead/rainbow varied among reaches, but were typically highest in the lower reaches of the Chiwawa River. In all years they most often used riffle and multiple channel habitats in the Chiwawa River, although we also found them associated with woody debris in pool and glide habitat. In tributaries they were generally most abundant in small pools. Those that we observed in riffles selected stations in quiet water behind small and large boulders or occupied stations in quiet water along the stream margin. In pool and multiple-channel habitats, we found age-0 steelhead/rainbow using the same kinds of habitat as age-0 Chinook salmon.
We estimated that 9,616 ( $\pm 13 \%$ of the estimated total) age- $1+$ steelhead/rainbow ( $4-8 \mathrm{in}$ ) lived in reaches of the Chiwawa Basin in August 2010 (Table 6). During the survey period 1992-2010, numbers of age-1+ steelhead/rainbow ranged from 2,533 to 22,130 (Figure 8; Appendix B). In most years we found these fish in nearly all reaches, but they were typically most numerous in lower reaches of the Chiwawa River. We observed age- $1+$ steelhead/rainbow mostly in pool, riffle, and multiple-channel habitats. Those that we observed in pools were usually in deeper water than age-0 steelhead/rainbow and Chinook. Like age-0 steelhead/rainbow, age-1+ steelhead/rainbow selected stations in quiet water behind boulders in riffles, but we generally did not find the two age groups together. Age-1+ steelhead/rainbow appeared to use deeper and

[^5]faster water than did age-0 steelhead/rainbow.
We estimated that steelhead/rainbow larger than 8 inches numbered 63 ( $\pm 27 \%$ of the estimated total) in the Chiwawa Basin in August 2010 (Table 7). During the period 1992-2010, steelhead/rainbow numbers ranged from 8 to 1,869 (Appendix B). Steelhead/rainbow larger than 8 inches were most abundant in the lower Chiwawa River; however, in 1992 and 1993, they were most abundant near campgrounds in Reaches 8, 9, and 10 (these were mostly hatchery fish planted near the campgrounds). We found very few in tributary survey reaches. Most of the steelhead/rainbow larger than 8 inches used deep pools ( $>5$ feet), and occupied stations near the bottom at the upstream end of pools.

## Bull Trout Abundance

We estimated, based on surface area, that at least 79 ( $\pm 32 \%$ of the estimated total) juvenile (2-8 in) bull trout lived in reaches of the Chiwawa River Basin in August 2010 (Table 8). We found most of these fish in the upper-most reaches and in tributaries of the Chiwawa River. During 1992-2010, numbers of juvenile bull trout ranged from 79 to 505 (Figure 9; Appendix B). These estimates and those for adult bull trout are incomplete because we did not sample the entire range of bull trout in all tributaries. We did not extend our surveys into the headwaters of the Chiwawa River because there were no juvenile Chinook there. Areas beyond the distribution of juvenile Chinook salmon are known to support bull trout, steelhead/rainbow, and cutthroat trout (USFS 1993). In addition, our estimates of bull trout abundance were based on daytime snorkel surveys, which may underestimate the actual abundance of bull trout. ${ }^{5}$ Several studies (e.g., Goetz 1994; Thurow and Schill 1996; Hillman and Chapman 1996; Bonar et al. 1997) have found bull trout population estimates based on nighttime snorkeling to be in some cases more accurate than daytime snorkeling, especially for juvenile bull trout. Our estimates of adult bull trout numbers may be more accurate than those for juveniles.

In all years we found most juvenile bull trout in the upstream reaches of the Chiwawa River. Of the reaches we surveyed, they were most numerous in Reaches $8-10$ on the Chiwawa River. We found the majority of these fish in multiple channels, pools, and riffles, and few in glides. They consistently occupied stations close to the stream bottom over rubble and small boulder substrate or near woody debris. This is similar to the observation of Pratt (1984) in the upper Flathead River Basin in Montana. She found that juvenile bull trout lay close to instream cover and that they tended to conceal themselves. As a result, she found it difficult to accurately estimate their numbers. Although this implies that we underestimated numbers of juvenile bull trout in the Chiwawa River, the relative distribution of juvenile bull trout is valid if we assume that we saw the same fraction of juveniles in all reaches (i.e., detection probability was the same across survey sites).
We estimated a total of 547 ( $\pm 15 \%$ of the estimated total) adult ( $>8 \mathrm{in}$ ) bull trout in reaches of the Chiwawa Basin in August 2010 (Table 9). In previous years, numbers ranged from 76 to 900 (Figure 9; Appendix B). As with juvenile bull trout, we found most of the adult bull trout

[^6]upstream from Reach 6; although they were found in nearly all reaches on the Chiwawa River. We found relatively few adult bull trout in tributaries of the Chiwawa River. Adult bull trout primarily used pools and multiple channel habitat, although most of the smaller adults (<10 in) used riffles. In all years we found few adult bull trout near campgrounds. There also appeared to be an inverse association between numbers of adult bull trout and numbers of age-0 Chinook salmon in pools in Reaches 7-10. That is, where we found large bull trout we generally observed few juvenile Chinook salmon.

## Abundance of Other Salmonids

In August 2010, we estimated that at least 147 brook trout, an exotic species closely related to the bull trout, occurred in the Chiwawa River, Chikamin Creek, Big Meadow Creek, Minnow Creek, and in the Little Wenatchee River survey areas. Brook trout occurred in the lower seven reaches on the Chiwawa River. In both the Chiwawa and Little Wenatchee rivers, brook trout usually used multiple channels. Few appeared to be bull trout/brook trout hybrids. In Chikamin, Minnow, and Big Meadow creeks, brook trout were most abundant in pools. Brook trout lengths ranged from 2-8 inches.

At least 254 westslope cutthroat trout occurred in the Chiwawa River, Rock Creek, and Phelps Creek survey areas in August 2010. These fish most often occurred in pools and multiple channel habitats. They ranged in size from 2-18 inches. Juvenile coho salmon were observed in Nason Creek.

We observed both juvenile and adult mountain whitefish in the Chiwawa River, Rock Creek, Phelps Creek, Nason Creek, and the Little Wenatchee River survey areas. In sum, at least 6,655 adult and 1,169 juvenile whitefish lived in these streams in August 2010. We found few whitefish in most tributaries to the Chiwawa River.

## Conclusion

This was the $18^{\text {th }}$ year of a study to monitor trends in juvenile spring Chinook production in the Chiwawa River Basin. As shown in Figure 3, numbers of juvenile Chinook salmon in the Chiwawa Basin have fluctuated widely over the 18-year period. Numbers of juveniles in 2001 and 2002 were some of the highest recorded, while numbers in the mid-1990s were some of the lowest. Interestingly, the highest spawning escapements (highest redd numbers) resulted in the lowest egg-parr survival rates (Appendix A). This is supported by the fact that the best approximating model clearly demonstrates a density-dependent relationship between seeding levels and juvenile production. Indeed, there is a significant negative relationship between parr per redd and numbers of redds in the Chiwawa Basin. This is an important observation because Objectives 1, 3, 4, and 7 and their associated hypotheses in the monitoring and evaluation plan (Murdoch and Peven 2005) are only valid when the supplemented population is below its carrying capacity.

The presence of density dependence in the early life stages of spring Chinook is not surprising. Rarely does density dependence appear in numbers of adult spring Chinook or on their spawning grounds. The Chiwawa Basin appears to have plenty of spawning habitat, as indicated by the large numbers of spawners and redds widely distributed throughout the basin during 2001 and 2002. However, those large spawning escapements did not translate into large numbers of
juveniles or smolts. Thus, density-dependent regulation appears to occur sometime during the early life stages of the fish, likely at the fry stage. It is possible that physical habitat (space) during higher flows when fry are emerging may limit juvenile Chinook production in the basin. Low nutrient levels and its effects on food (macroinvertebrates) production may also be a limiting factor in the basin. If spawning escapements remain relatively high, marine-derived nutrients should increase in the basin, resulting in more food for juvenile Chinook salmon.

[^8]Table 4. Summary of the six productivity models of juvenile (age-0) Chinook salmon in the Chiwawa Basin. Models are shown, including the number of parameters $(K), \mathrm{AIC}_{\mathrm{c}}$ values, $\mathrm{AIC}_{\mathrm{c}}$ difference scores $\left(\Delta_{\mathrm{i}}\right)$, the likelihood of the model given the data $\left(£\left(g_{i} \mid x\right)\right)$, Akaike weights $\left(w_{i}\right)$, and adjusted $R^{2}$ values. The sample size ( $n$ ) for all models was 18 . Models describe the relationship between juvenile Chinook numbers (dependent variable) and redd numbers (independent variable).

| Model | $\boldsymbol{K}^{\boldsymbol{a}}$ | $\mathbf{A I C}_{\mathbf{c}}$ | $\boldsymbol{\Delta}_{\mathbf{i}}$ | $£\left(\boldsymbol{g}_{\boldsymbol{i}} \mid \boldsymbol{x}\right)$ | $\boldsymbol{w}_{\boldsymbol{i}}$ | ${\text { Adj } \boldsymbol{R}^{\mathbf{2}}}$Beverton-Holt |
| :--- | :---: | :---: | :---: | :---: | :---: | :---: |
| Ricker | 3 | -87.11 | 0.00 | 1.00 | 0.90 | 0.81 |
| Gamma $^{\text {b }}$ | 4 | -81.11 | 5.99 | 0.05 | 0.05 | 0.73 |
| Cushing | 3 | -80.14 | 6.97 | 0.03 | 0.03 | 0.75 |
| Smooth Hockey Stick | 3 | -45.13 | 41.98 | 0.00 | 0.00 | 0.80 |
| Density Independent | 2 | 25.09 | 112.19 | 0.00 | 0.00 | -0.06 |

${ }^{\mathrm{a}} \boldsymbol{K}$ is the number of structural parameters in the model plus 1 for $\sigma^{2}$.
${ }^{\mathrm{b}}$ The $\gamma$ parameter in the Gamma model was greater than 0 , which means that this model is nearly identical to the Ricker model.
The reason it did not rank higher than the Ricker model is because the Gamma model contains an extra parameter, which means that it has less bias and greater variance than the Ricker model (less parsimonious).

Table 5. Estimated mean densities (fish $/$ hectare and fish $/ \mathrm{m}^{3}$ ), total numbers, $95 \%$ confidence bounds on total numbers, and error of the estimated total number of age-0 $(<4 \mathrm{in})$ steelhead/rainbow in reaches in the Chiwawa River Basin, Washington, August 2010.

## Subject: 2010 Chiwawa and Wenatchee River Smolt Estimates

Smolt monitoring programs in the Wenatchee Basin were intended to estimate the number of naturally produced migrating smolts at either the subbasin (i.e., Wenatchee) or watershed scale (i.e., Chiwawa) depending on the target stock (Table 1). In addition, population estimates of hatchery sockeye emigrating from Lake Wenatchee were used to calculate post release survival (i.e., subyearling parr to yearling smolt). The size of smolt traps operated was determined by water depth and river discharge at each of the locations. The number of smolt traps operated was determined by the expected trap efficiency. Smolt traps were located downstream from all (i.e., Chiwawa spring Chinook, Wenatchee spring Chinook, and Wenatchee sockeye), or the majority (i.e., Wenatchee summer Chinook and Wenatchee steelhead) of the spawning areas (Figure 1).

Table 1. Target stocks and corresponding smolt trapping locations used in 2010.

| Stock | Smolt trap location | Smolt trap |  |
| :--- | :--- | :---: | :---: |
|  |  | Number | Diameter (m) |
| Chiwawa spring Chinook | Chiwawa | 1 | 2.6 |
| Wenatchee sockeye | Lake Wenatchee | 2 | 1.5 |
| Wenatchee spring Chinook | Monitor (Lower Wenatchee) | 2 | 2.6 |
| Wenatchee summer Chinook | Monitor (Lower Wenatchee) | 2 | 2.6 |
| Wenatchee steelhead | Monitor (Lower Wenatchee) | 2 | 2.6 |

Figure 1. Locations of the upper Wenatchee (Lake Wenatchee Trap), Chiwawa, and lower Wenatchee River (Monitor Smolt Trap) smolt traps.

## Methods

Fish were removed from the trap at a minimum every morning and placed in an anesthetic solution of MS-222. Fish were identified to species and counted. Non-target species were allowed to fully recover in fresh water prior to being released in an area of calm water downstream from the smolt trap. Target species were held in separate live boxes when needed for mark/recapture efficiency trials conducted in the evening.

Fork length was measured to the nearest millimeter and weight to the nearest 0.1 g . A Fulton type condition factor $\left(\mathrm{WH} 10^{5} / \mathrm{FL}^{3}\right)$ was calculated for all target species. The degree of smoltification (parr, transitional, or smolt) was assessed by visual examination. Juvenile spring Chinook and steelhead were classified as parr if parr marks were distinct, transitional if parr marks were not distinct, and smolts if parr marks were not visible and the fish exhibited a silvery appearance.
Mark/recapture efficiency trials were conducted throughout the trapping season. The frequency of mark/recapture trials was dependent on the number of fish captured (i.e., no less than 100) and the river discharge. These trials were conducted over the widest range of discharge possible (interval depends on trap location). Fish utilized for mark/recapture trials were marked by clipping the tip of either the upper or lower lobe of the caudal fin or were PIT tagged by Chelan County PUD personnel. Chinook fry (i.e., FL < 50 mm ) used in mark/recapture trials were dyed
using a Bismark brown solution. Marked fish were distributed evenly on both sides of the river in pools or in calm pockets of water around boulders. In the case of the upper Wenatchee River trap, marked fish were transported and released into Lake Wenatchee. Marked fish were released between 1800 h and 2000 h . All recaptures of marked fish typically occurred within 48 h after each trial. Emigration estimates were calculated using estimated daily trap efficiency derived from the regression formula using trap efficiency (dependent variable) and discharge (independent variable).
Trap efficiency was calculated using the following formula:

$$
\text { Trap efficiency }=E_{i}=R / M i,
$$

Where $E_{i}$ is the trap efficiency during time period $i ; M_{i}$ is the number of marked fish released during time period $i$; and $R_{i}$ is the number of marked fish recaptured during time period $i$. The number of fish captured was expanded by the estimated daily trap efficiency $(e)$ to estimate the daily number of fish migrating past the trap $\left(N_{i}\right)$ using the following formula:

$$
\text { Estimated daily migration }=\hat{N}_{i}=C_{i} / \hat{e}_{i}
$$

where $N_{i}$ is the estimated number of fish passing the trap during time period $i ; C_{i}$ is the number of unmarked fish captured during time period $i$; and $e_{i}$ is the estimated trap efficiency for time period $i$ based on the regression equation.

The variance for the total daily number of fish migrating past the trap will be calculated using the following formulas:

Variance of daily migration estimate $=$

$$
\operatorname{var}\left[\hat{N}_{i}\right]=\hat{N}_{i}^{2} \frac{\operatorname{MSE}\left(1+\frac{1}{n}+\frac{\left(X_{i}-\bar{X}\right)^{2}}{(n-1) \mathrm{s}_{\mathrm{x}}^{2}}\right)}{\hat{e}_{i}^{2}}
$$

where $X_{i}$ is the discharge for time period $i$, and $n$ is the sample size. If a relationship between discharge and trap efficiency was not present (i.e., $P<0.05 ; r^{2} \sim 0.5$ ), a pooled trap efficiency was used to estimate daily emigration:

$$
\text { Pooled trap efficiency }=e_{p}=\sum R / \sum M
$$

The daily emigration estimate was calculated using the formula:

$$
\text { Daily emigration estimate }=\hat{N}_{i}=C_{i} / e_{p}
$$

The variance for daily emigration estimates using the pooled trap efficiency was calculated using the formula:

Variance for daily emigration estimate $=\operatorname{var}\left[\hat{N}_{i}\right]=\hat{N}_{i}^{2} \frac{e_{p}\left(1-e_{p}\right) / \sum M}{e_{p}^{2}}$

The total emigration estimate and confidence interval was calculated using the following formulas:

$$
\begin{gathered}
\text { Total emigration estimate }=\sum \hat{N}_{i} \\
95 \% \text { confidence interval }=1.96 \times \sqrt{\sum \operatorname{var}}\left[\hat{N}_{i}\right]
\end{gathered}
$$

## Results

## Chiwawa River Smolt Trap

## 2008 Brood Year

The Chiwawa River smolt trap was located approximately 1 km upstream from the confluence with the Wenatchee River. The smolt trap operated between 5 March and 22 November. During that time period the trap was inoperable for 20 days as a result of high river flows, debris, snow/ice, mechanical failure, or statewide furlough days. During breaks in operation, the estimated number of Chinook captured was calculated from the mean number of fish captured two days prior and two days after the break in operation. The trap was operated in two positions dependent on river discharge (i.e., lower $>12 \mathrm{~m}^{3} / \mathrm{s}$ and upper $<12 \mathrm{~m}^{3} / \mathrm{s}$ ). Daily trap efficiencies were estimated from two regression models (independent variable $=$ discharge) depending on trap position and age class (i.e., subyearling and yearling Chinook).

Wild yearling spring Chinook (2008 brood) were primarily captured between 5 March and 1 June (Figure 2). 6,482 yearling Chinook were captured (Appendix A) and an estimated 6,779 yearling Chinook would have been captured if the trap had operated without interruption. Mortality for the season totaled 23 yearling spring Chinook ( $0.4 \%$ ). Seven mark/recapture efficiency trials were conducted in the lower position with a mean (SD) trap efficiency of 27.3 (0.04) \%. In 2010, mark/recapture trials could not be conducted at all required discharge levels due to large catch rates of hatchery Chinook. Therefore, efficiency trials were combined with 2007, 2008, and 2009 trials in order to expand the population models utility over a greater range of river discharge. The 2010 regression model for the lower position ( $r^{2}=0.70, P<0.001$ ) was used to estimate yearling Chinook emigration. The estimated number (95\% C.I.) of yearling Chinook that emigrated from the Chiwawa River in 2010 was $35,023( \pm 9,438)$.

## 2009 Brood Year

Wild subyearling spring Chinook were captured between March 5 and November 22, with major peaks occurring in August, September, and November (Figure 2). We captured 13,344 subyearling Chinook and estimated 14,101 subyearling Chinook would have been captured if the
trap had operated without interruption (Figure 2). Mortality for the season totaled 64 subyearling spring Chinook ( $0.48 \%$ ). Thirteen mark/recapture efficiency trials were conducted with a mean (SD) trap efficiency of $15.4(0.08) \%$, which provided a current year regression model (i.e., upper trap position; $r^{2}=0.55, P<0.01$ ). However, subyearling Chinook were also captured while the trap was operated in the lower position. Hence, a separate regression model from 2002 was used for that time period ( $r^{2}=0.62, P<0.01$ ). In 2010, the estimated number ( $95 \%$ C.I.) of subyearling spring Chinook (including fry) that moved downstream of the Chiwawa River smolt trap during the sampling period was $103,185( \pm 15,166)$.

The proportion of subyearling Chinook that were captured and classified as fry, was greater in 2010 (58\%) than in 2009 ( $45 \%$ ) or in 2008 ( $16 \%$ ). Typically the number of fry captured comprises less than $3 \%$ of the total number of Chinook captured for any given brood year. The large proportion of fry captured in 2010 and 2009 was attributed to a combination of large escapement, proximity of redds to the trapping location, high water velocity and discharge during the emergence period. As of yet, we have not determined if fry captured in the smolt trap migrate upstream at a later date and rear in the Chiwawa River or reside downstream of the smolt trap until the following spring and emigrate as yearling smolts. Hillman and Miller (2002) reported large numbers of subyearling Chinook in tributaries of the Chiwawa River where no spawning had been reported. These data suggest considerable movement during the summer rearing period. Due to the high likelihood that fry do migrate upstream and reside in the Chiwawa River, fry have not been included in our emigrant production estimates. Excluding the fry from the estimate, the number of subyearling spring Chinook that emigrated from the Chiwawa River was $31,913( \pm 5,779)$.

Figure 2. Daily number of Chiwawa River spring Chinook smolts, parr, and fry captured in 2010.

Emigrant Survival

The estimated total egg deposition was calculated by multiplying the mean fecundity of the 2008 brood spawners (WDFW, unpublished data) by the total number of redds found during surveys in the Chiwawa River basin in 2008 (Murdoch et al. 2008). Egg-to-emigrant survival was calculated by dividing the estimated egg deposition by the total number of subyearling (excluding fry) that emigrated in 2009 and yearling spring Chinook that emigrated in 2010. The estimated egg-to-emigrant survival for the 2008 brood Chiwawa spring Chinook was $3.8 \%$ (Table 2).

## Length and Weight

Individual length and weight measurements were recorded from a sample of the daily catch. The mean fork length (SD) of captured yearling and subyearling Chinook (fry excluded) was 91.52 (7.81) mm and 74.58 (13.04) mm, respectively (Table 3).

* Parr only

## Nontarget Salmonids

During the trapping period, 210 steelhead smolts and 1,016 steelhead/rainbow parr were captured. Mortality for the season totaled 8 steelhead juveniles ( $0.65 \%$ ). The mean fork length (SD) of steelhead parr and smolts captured was 90.15 (39.46) mm and 124.38 (34.47) mm, respectively (Table 4). Bull trout also comprised a large proportion of incidental species captured. During the trapping period, 45 adult ( $>300 \mathrm{~mm}$ ) and 499 juvenile bull trout were captured (Table 5). Low numbers of fish captured prevented us from estimating the total number of steelhead and bull trout that emigrated from the Chiwawa River during the sampling period. Mortality for the season totaled 10 juvenile bull trout (2.0\%) and 2 adult bull trout (4.4\%). The monthly totals of all fish captured are listed in Appendix A.

## Upper Wenatchee River Smolt Trap

The upper Wenatchee River smolt traps were located approximately 0.5 km below the outlet of Lake Wenatchee. The trap operated nightly between 12 March and 8 July 2010. We captured 60,792 wild and 1,909 hatchery sockeye smolts during the sampling period (Figure 3). Mortality during the season totaled 480 wild sockeye $(0.79 \%)$ and 2 hatchery sockeye $(0.10 \%)$. We also captured 569 wild spring Chinook smolts, and 95 juvenile Steelhead. Mortality totaled six wild juvenile Steelhead ( $6.3 \%$ ) and 5 wild yearling Chinook ( $0.87 \%$ ). There was no mortality of bull trout captured during the sampling period. The monthly totals of all fish captured are listed in Appendix B.

Eight mark/recapture efficiency trials with wild and hatchery sockeye were conducted during the sampling period. A combined total of 7,410 wild and hatchery sockeye were marked (i.e., caudal fin clip) and released into Lake Wenatchee. A combined total of 39 wild and hatchery sockeye were recaptured. A delay in migration and subsequent recapture of the marked fish from Lake Wenatchee negatively affected the relationship between discharge and trap efficiency (i.e., unequal probability of recapture). Both the hatchery and wild sockeye smolt production estimates were calculated using a wild and hatchery pooled daily trap efficiency ( $0.53 \%$ ). The estimated smolt production ( $95 \%$ C.I.) for wild sockeye was $11,551,430( \pm 805,182)$. Age classes of wild sockeye were determined from scales collected randomly from the run (Table 6). Egg deposition was calculated based on the female to male ratio and spawning escapement determined at Tumwater Dam multiplied by fecundity of the broodstock (C. Deason, WDFW, personal communication). Historical egg-to-smolt survival rates for wild Wenatchee sockeye have ranged between $1.2 \%$ and $21.2 \%$ (Table 7).

The estimated number ( $95 \% \mathrm{CI}$ ) of hatchery sockeye that emigrated from Lake Wenatchee was $368,600( \pm 30,120)$, greater than the actual number of hatchery sockeye released $(154,772)$. This was the fourth brood year in which all hatchery sockeye parr were released at a similar size and time since 1999, and the fourth brood year since 1995 where estimated emigration exceeded actual release. Due to our estimate being greater than the actual number of hatchery parr released we adjusted our emigrant estimate and assumed that survival was $100 \%$ (Table 8). Overestimation of the smolt migration is likely due to an underestimate of actual trap efficiency and probability of trap avoidance. Additional studies are needed to determine the source of error in trap efficiency estimates and possible alternatives.

## Lower Wenatchee River Smolt Trap

The lower Wenatchee River smolt traps were located at the West Monitor Bridge (rkm 9.6). The trap operated nightly between 4 February and 20 July. However, due to heavy debris and/or high flow, both traps were not operational for 19 days (i.e., 17 May through 21 May, 3 June through 6 June, 9 June through 11 June, 14 June through 16 June, 25 June through 26 June, and 12 July through 13 July). One trap was not operational for an additional 68 days (i.e., 21 April through 25 April, 15 May through 6 July, and 8 July through 17 July).

We captured 1,079 wild spring Chinook (Figure 4) and 484 parr and smolt steelhead (Figure 5). A total of 215 steelhead fry were captured. A total of 50,685 subyearling Chinook were captured (Figure 4) comprising $97.9 \%$ of the total number of wild juvenile Chinook captured in 2010. We also captured 3,153 wild sockeye (Figure 6). Mortality during the trapping period consisted of 5 yearling Chinook ( $0.5 \%$ ), 361 wild subyearling Chinook ( $0.7 \%$ ), and two steelhead fry ( $0.9 \%$ ). Hatchery fish captured totaled 43,613 yearling Chinook, 2,735 steelhead and 440 sockeye. The monthly totals of all fish captured are listed in Appendix C. Smolt production estimates for salmon and steelhead were calculated using efficiency trials conducted with subyearling Chinook, yearling hatchery Chinook, and yearling hatchery coho. Mark/recapture trials were conducted when river discharge changed between 14 and $28 \mathrm{~m}^{3} / \mathrm{s}$ or the trap position had changed. Low abundance of other target species precluded their use in mark/recapture trials.

Smolt production estimates were calculated using separate regression models (independent variable $=$ river discharge) for each trap position and species. However, when too few trials for a given position or species were conducted, efficiency trials from previous years were incorporated into the regression model. Until the relative abundance of wild yearling Chinook and steelhead increases, or trap efficiency significantly increases such that an adequate number of the target species are captured, surrogates must be used in trap efficiency trials. Estimates for yearling Chinook and steelhead incorporated regression models developed with hatchery coho and hatchery Chinook for both the trap positions ( $r^{2}=0.43, P<0.01 ; r^{2}=0.65, P<0.01$ ).
Subyearling Chinook were captured in sufficient numbers such that regression models were developed using only subyearling Chinook when the trap was operated in both operating positions, however to encompass a wider range of river discharge, previous year mark groups were also used $\left(r^{2}=0.30, P<0.01 ; r^{2}=0.89, P<0.01\right)$. The smolt production estimate ( $95 \% \mathrm{CI}$ )
for wild yearling and subyearling Chinook was $82,137( \pm 87,931)$ and $6,695,977( \pm 2,435,120)$, respectively. The 2008 brood egg-to-smolt survival for Wenatchee spring Chinook was $1.27 \%$ (Table 9). The smolt production estimate for Wenatchee steelhead was $36,826( \pm 22,782)$ and the 2006 brood emigration, completed in 2010, had an egg-to-smolt survival of $1.72 \%$ (Table 10).

## Discussion

## Upper Wenatchee River Smolt Trap

Wild and hatchery Sockeye were used in eight mark/recapture efficiency trials. While significant numbers of sockeye were caught to perform trials at variable discharge levels, a flow stratified linear model was not obtained (i.e. $\mathrm{P}>0.05 \& \mathrm{R}^{2}<0.50$ ). A delay in migration and subsequent recapture of the marked fish from Lake Wenatchee negatively affected the relationship between discharge and trap efficiency (i.e., unequal probability of recapture). Therefore, the pooled trap efficiency of $0.53 \%$ was used to calculate sockeye smolt production estimates. It is likely this is an underestimate of actual trap efficiency, due to the unequal probability of recapture, and thus led to overestimated smolt migrations. The pooled trap efficiency for 2010 was also significantly lower than previous years that ranged from $0.9 \%$ to $1.0 \%$. This contributed to a high measure of inaccuracy in our estimate of both wild and hatchery Sockeye. The trap site will remain the same for 2011 but be moved approximately 8 km downstream for 2012 with the goals of obtaining a flow stratified model, reducing migration delays and predation during efficiency trials, and increasing our catch of Sockeye and other salmonids.

## Lower Wenatchee River Smolt Trap

Low abundance of spring Chinook and steelhead precluded their use for mark/recapture trials. Hatchery Chinook were used as surrogates for mark/recapture trials, which were conducted at various levels of river discharge or if the trap position had changed. Smolt production estimates were calculated using separate regression models (independent variable = river discharge; dependent variable $=$ trap efficiency) for each of the two trap positions. Mark/recapture trials conducted in 2010 were too few at the varying river discharge to obtain a useable model. Therefore, trials from previous years (i.e., 2001-2009) were used to increase the sample size in the model.

Hatchery Coho catch numbers were significantly lower in 2010 than previous years while hatchery Chinook numbers were significantly higher (Appendix C), therefore mark/recapture trials were carried out with hatchery Chinook only. Previously, high abundance of hatchery Coho permitted their use as surrogates in mark/recapture trials. Hatchery Chinook and Coho will continue to be used as surrogates in trap efficiency trials until the relative abundance of wild spring Chinook and steelhead increase sufficiently to allow species-specific trials.

The high confidence interval for yearling spring Chinook in $2010(82,137( \pm 87,931))$ can be explained by low trap efficiency which inversely contributes to high variance in the estimate. A large portion of the yearling Chinook catch occurred while discharge ranged from 42.5 to 85.0 $\mathrm{m}^{3} / \mathrm{s}$, where efficiencies ranged from $0.95 \%$ to $1.96 \%$. Fish were also caught outside the discharge range of our model, adding to inaccuracy. The majority of wild Steelhead smolts were captured at discharge ranges ( $85.0-141.6 \mathrm{~m}^{3} / \mathrm{s}$ ) where the trap experienced higher efficiencies (2.0-3.8\%). This resulted in a comparatively lower confidence interval for migrating Steelhead smolts $(36,826( \pm 22,782))$. This same trend can be applied to sub yearling Chinook estimates, where large catch numbers during discharge ranges resulting in higher efficiencies led to a
comparatively lower confidence interval (6,695,977 $( \pm 2,435,120)$ ).
Although the high variability in discharge leads to high confidence intervals we feel our estimates are acceptable because the regression models used to generate them are significant (yearling estimates, $r^{2}=0.43, P<0.01 ; r^{2}=0.65, P<0.01$; sub yearling estimates, $r^{2}=0.30, P<$ $0.01 ; r^{2}=0.89, P<0.01$ ). Improvements to our variance equation will continue to be explored along with other variables that may influence mark/recapture trials and subsequently affect our confidence intervals. Investigation of such parameters and vigilance in sampling methods will continue to be the focus of upcoming seasons.

## Chiwawa River Smolt Trap

The 2009 brood year subyearling spring Chinook model was developed with 2010 mark/recapture trials only. A significant relationship was obtained between river discharge and trap efficiency ( $r^{2}=0.55, P<0.01$ ). Thirty-nine trapping days fell out of the discharge range of the model, however during these time periods only 58 subyearling parr were caught. This resulted in small variance during these discharge ranges.

Only five mark/recapture trials were conducted for the 2008 brood yearling spring Chinook estimate and a relationship between discharge and efficiency was significant. However, discharge for that model only ranged from 5.3 to $8.9 \mathrm{~m}^{3} / \mathrm{s}$. Therefore, mark groups from 2010 were incorporated into a combined 2007 through 2010 linear regression ( $\mathrm{r}^{2}=0.70, \mathrm{P}<0.01$ ). This enabled the models utility over a range of discharges from 3.8 to $32.5 \mathrm{~m}^{3} / \mathrm{s}$.

Since the spring of 2008 an instream PIT tag antennae array has been in operation directly upstream from the Chiwawa trap site. We have collected numerous amounts of data including all mark recapture efficiency trials conducted at the trap site, adult spawning migration and other juvenile movement detections. Analysis of these data will begin in 2011 with emphasis on exploring subyearling Chinook movement during winter months.

## APPENDIX D

Wenatchee Steelhead Spawning Ground Surveys, 2010

# STATE OF WASHINGTON <br> DEPARTMENT OF FISH AND WILDLIFE <br> FISH PROGRAM - SCIENCE DIVISION <br> SUPPLEMENTATION RESEARCH TEAM <br> 3515 Chelan HWY, Wenatchee, WA 98801 <br> Voice (509) 663-9678 FAX (509) 662-6606 

1 March 2011

To: Distribution List
From: Andrew Murdoch and Chad Herring
Subject: 2010 Wenatchee River Basin Steelhead Spawning Ground Surveys
Summer steelhead migrate to their spawning grounds as early as nine months prior to spawning. Run escapement estimates of summer steelhead counted at Columbia River dams or at Tumwater Dam in the Wenatchee River may not accurately reflect the size of the spawning population because of fallback and prespawn mortality that may occur prior to spawning. English et al. (2003) reported fallback rates for Rock Island (4.9\%) and Rocky Reach ( $6.5 \%$ ) dams were similar, but no information regarding Tumwater Dam was reported. In the same study, survival to spawning was not explicitly calculated, but kelting rates for the Wenatchee River ranged between $68 \%$ and $77 \%$ and may serve as a minimum survival rate. Keefer et al. (2008) conducted a more comprehensive study throughout the Columbia Basin and reported mortality rates of summer steelhead that overwintered in the Columbia River or tributaries was $14.5 \%$ and $18.9 \%$, respectively.

Redd counts may be used to calculate a more accurate estimate of the spawning population, but requires knowledge concerning the number of redds constructed per female and the number of fish per redd. Female steelhead have been reported to construct multiple redds, ranging between 1.02 and 6.91 redds (Reingold 1965; Gallagher and Gallagher 2005; Kuligowski et al. 2005). Large variation in the reported number of redds per female within and across populations may be natural or more simply a lack of precision in the methodology used (e.g., errors in redd counts or the number of female spawners). While the sex ratio may be an appropriate surrogate for the number of fish per redd under the assumption females construct a single redd. However, if female steelhead construct multiple redds, it is also likely male steelhead spawn at multiple redd locations with either the same or different females resulting in an overestimate of the spawning population. An estimate of the spawning population coupled with other population specific information (i.e., ratio of hatchery and wild spawners and age composition) are critical data needed to assess the productivity of the population (i.e., recruits per spawner).

Our objectives in conducting steelhead spawning ground surveys were to 1 ) determine spawn timing of naturally spawning steelhead (both hatchery and wild origin) and 2) estimate the abundance of redds constructed within selected tributaries and 3) calculate
error rates in redd detection and determine what factors (e.g., environmental or habitat variables) affect observer efficiency. We also examined the relationship between run escapement upstream of Tumwater Dam (i.e., female and total) and redd counts as a method of assessing the precision of our estimates.

## Methods

## Run Escapement

Steelhead migrating upstream of Tumwater Dam were captured, sampled (sex, length, weight, scales), and PIT tagged as part of a separate study. Gender was determined using ultrasonography and secondary sexual characteristics (i.e., kype, coloration, body shape). Origin was determined using hatchery marks (i.e., fin clip, VIE, CWT, or eroded fins) or scale pattern analysis if no marks were identified.

## Spawning Ground Surveys

Spawning grounds surveys were primarily concentrated in the upper Wenatchee Basin because all hatchery fish were released upstream of Tumwater Dam. Peshastin Creek was included in our surveys because it was identified as a potential reference stream (i.e., no hatchery releases since 1998) for the Wenatchee Basin. Survey methodology involved surveying non-random index areas, defined as major spawning area(s) for each stream. Index areas included in the redd observer efficiency study were surveyed every third day, with the remaining index areas surveyed as frequently as once a week. Redds were either individually flagged or in the case of large aggregates of localized spawning, mapped and numbered sequentially. All redds were also geo-referenced using handheld global positioning devices. Between 2000 and 2003, the number of index areas has increased as more information became available. Beginning in 2004, survey methodology has remained similar. Hence, direct comparisons of redd counts to years before 2004 may not be appropriate.

Index area spawning ground surveys were conducted by foot or raft on the Wenatchee River and most major tributaries (Appendix A). For each index area, the same surveyor(s) conducted all weekly surveys. However, when the end of spawning within an index area was thought to be nearly complete, a different observer (i.e., naïve) surveyed the index area to determine the number of redds still visible at the end of spawning. At approximately the same time, non-index areas within a reach or stream were also surveyed. The total number of redds in non-index areas was estimated by dividing the number of redds found in non-index areas by the proportion of redds still visible inside the index area. The reach total redd count was calculated by combining the number of redds in the index area and the estimated number of redds in the non-index areas. Murdoch and Peven (2005) provide a more detailed description of the methodology (Appendix F, Task 7-3).

The sex ratio of the entire population upstream of Tumwater Dam was used as the redd expansion factor (i.e., number fish per redd). The sex ratio was calculated using the number of female and male steelhead passed upstream of Tumwater Dam during trapping
and video count operations. Spawning escapement was estimated by multiplying the estimated total number of redds by the number of fish per redd. Linear regression analysis was used to examine the relationship between run escapement estimates, index area redd counts, and total redd counts upstream of Tumwater Dam. Fallback rates at Tumwater Dam were calculated based on the number of PIT tagged steelhead recaptured or tagged at Tumwater Dam that were detected downstream of Tumwater Dam prior to spawning divided by the total number of PIT tagged steelhead.

## Observer Efficiency Study

In 2010, a three year study was initiated to estimate redd observer variability generally following the methods described in Thurow and McGrath (2010). A total of six index areas within the Wenatchee River Basin were selected for the observer efficiency study based on several biological, environmental, and habitat related variables that were thought to potentially influence redd detection (Table 1). For each study reach, hereafter referred as the census reach, the same surveyor(s) was used to conduct surveys every three days.

Table 1. Proposed study reaches and relevant data for Wenatchee Basin steelhead

| Channel complexity | Simple | Simple | Complex | Complex | Simple | Simple |

All census reaches had ten equidistant habitat transects to quantify habitat variables that may affect observer efficiency. Habitat transect data was collected during the first survey of each census reach. At each habitat transect a waypoint was taken using a hand held GPS unit. Measurements at each transect include wetted channel width, stream depth at $1 / 4,1 / 2$ and $3 / 4$ of the wetted channel width, and proportion of substrate type. In between each habitat transect a count was made of large woody debris, gravel bars, islands and the percentage of substrate with overhead cover. During a census survey all features were
georeferenced using a hand-held GPS unit and denoted on aerial photographs. Features were then classified as either redds, old redds, test or incomplete redds, or a hydrologic feature. During or after peak spawning for each census reach, multiple independent (naïve) observers conducted surveys and counted all redds observed. Independent observers georeferenced and denoted on aerial photographs all features that were believed to be steelhead redds. ArcGIS and aerial photographs were used to compare features believed to be redds identified by independent surveys to census survey features that were visible during the time the independent survey was conducted. Redds identified by the independent surveyors were then classified as true redd, a visible redd that was omitted, or a false identification.

## Steelhead Redd Life

Because surveys were not conducted past the end of the spawning period, redd life for many redds could not be fully determined (i.e., redds were still visible on the last survey day). Hence, estimates of mean redd life for a specific reach would be biased if only redds with a complete redd life were included. High escapement in 2010 also influenced redd life via redd superimposition. We attempted to address both of these factors by calculating redd life using two different approaches. Standard redd life was defined as the number of days a redd was visible and were not affected by redd superimposition or a freshet. Standard redd life includes those redds that were still visible before the first major freshet of the season. Operational redd life is the number of days a redd is visible throughout the spawning period regardless of cause (i.e.., natural periphyton growth, redd superimposition or freshet).

## Steelhead Spawning Location and Timing

The spawning distribution and timing of hatchery and naturally produced steelhead was assessed using colored anchor tags (origin specific) inserted at trapping locations (Priest Rapids, Dryden and Tumwater Dams). During spawning ground surveys, observations of tagged females were correlated with redd location and date. Comparisons of spawning location were made by stream (t-test) and by reach (ANOVA) using georeferenced redd locations converted to the distance ( km ) upstream from the mouth of the tributary. Because spawn timing is influenced by water temperature, an analysis of covariance was used to determine the influence of elevation on spawn timing. In cases where elevation did not significantly influence spawn timing, comparison of spawn date were compared using t-tests.

## Results

## Run Escapement

The estimated steelhead run escapement upstream of Tumwater Dam was 2,270 fish that included 7 fish detected on videotape, 13 surplus broodstock, and 2,250 trapped and released upstream. Run escapement in 2010 was $27 \%$ greater than in 2009, and was $53 \%$ greater than the previous 5 -year average of 1,484 fish (Table 1). A greater proportion of male than female steelhead were observed at Tumwater Dam resulting in a fish per redd value of 2.33, assuming each female constructed a single redd. Of those steelhead
released upstream of Tumwater Dam 35\% $(N=787)$ were determined to be naturally produced.

## Spawning Ground Surveys

A below average snow pack coupled with cool air temperatures led to below average stream flows for most of the survey season. During the third week of April an increase in air temperature resulted in a temporary increase in stream flow resulting in poor survey conditions for approximately 4 days. After the second week of May, air temperatures increased such that snowmelt resulted in elevated water conditions for the remainder of the spawning period. Overall, survey conditions in 2010 were less than optimal compared to previous years. Poor environmental conditions (i.e., snow, rain, wind and clouds) were more common in 2010 and likely had a negative impact on redd detection rates.

Steelhead began spawning during the first week of March in Peshastin Creek, the second week of March in the Wenatchee River and Icicle River and third week of March in Nason Creek. Spawning progressed upstream as water temperatures increased. Spawning activity appeared to begin once the mean daily stream temperature reached $\sim 4.4^{\circ} \mathrm{C}$ and was observed in water temperatures ranging from 3.1-9.0 ${ }^{\circ} \mathrm{C}$. Steelhead spawning peaked in Peshastin Creek the second week of April. Peak spawning occurred the third week in April and the fourth week in April for the Wenatchee River and Nason Creek, respectively (Appendix B).

The estimated number of redds in the Wenatchee Basin increased 46\% between 2009 ( $N$ $=662)$ and $2010(N=969)$ and was $149 \%$ greater the 5 -year average of 389 redds (Table 2). In 2010, the proportion of redds in Nason Creek ( $27.9 \%$ ) was less than the 5 -year mean ( $31.5 \%$; Table 2). Redd distribution in Nason Creek continues to primarily be occurring in the middle two reaches (77\%; Appendix D1). Steelhead redds observed in the Chiwawa River were also found in locations consistent with previous years (Appendix D2). The proportion of redds found in all streams upstream of Tumwater Dam decreased from a high of $96 \%$ in 2006 to $75 \%$ in 2010 (Appendix D3). The number of redds in Peshastin Creek increased 269\% between 2009 and 2010 (Appendix D4). The number of steelhead redds in Icicle Creek, another major spawning tributary downstream of Tumwater Dam, increased in 2010 and was $18 \%$ greater than the number of redds observed in 2009. While the overall number of redds in the Wenatchee River increased from 327 in 2009 to 380 in 2010, the proportion of all redds in the Wenatchee River decreased from $49.4 \%$ in 2009 to $39.2 \%$ in 2010. However, the proportion of redds found within index and non-index areas upstream of Tumwater Dam in 2010 ( $84 \%$ ) was higher than the 9 year average ( $78 \%$ ), but within the observed range (Table 3).

Table 1. Total number, gender, and sex ratio of steelhead migrating upstream of Tumwater Dam between 2001 and 2010. Sex ratio in 2001 was determined by the number of fish passed and collected during broodstock collection at Tumwater and Dryden dams. For 2002-2008, gender was determined visually at Tumwater Dam. For 2009 and 2010, gender was determined visually and/or by ultrasound.

Female and total escapement explained a similar proportion of the variation in the estimated total number of redds (Figure 1). Given the variation in sex ratios and that only female steelhead construct redds, we would expect female escapement to explain a greater proportion of the variation in number of redds. This would suggest that the mean number of redds constructed by a female is relatively constant.

Figure 1. Relationship between steelhead run escapement (total and female) upstream of Tumwater Dam and total redd counts.

However, total run escapement explained a lesser proportion of the variation in index redd counts than total redd counts (Figure 2). As run escapement increases, habitat within the index areas may be near capacity and subsequently a greater proportion of redds are found outside index areas.

Figure 2. Relationship between steelhead run escapement upstream of Tumwater Dam and total and index area redd counts.

## Spawning Escapement

In 2010, $66 \%$ of the steelhead migrating above Tumwater Dam were accounted for on spawning grounds compared to the 5-year average (2005-2009) of $44 \%$ (Table 4). While environmental conditions do affect the accuracy of our estimates, other factors also contribute to the differences observed between run and spawning escapement estimates that can be estimated or quantified (i.e., prespawn mortality and fallback). Because no estimate of survival to spawning is available for steelhead in the Wenatchee Basin, we assumed that survival to spawning was at a minimum similar to that of steelhead overwintering in lower Columbia River tributaries (i.e., Deschutes and John Day) reported by Keefer et al (2008). Actual survival in the Wenatchee River may be considerably lower than that reported by Keefer et al. (2008) as a result of colder water temperatures and depleted energy reserves attributed to a greater migration distance.

While direct enumeration of steelhead upstream of Tumwater Dam is possible, it may not be appropriate to assume that all steelhead that migrate upstream of Tumwater Dam spawn upstream of Tumwater Dam (i.e., fallback). Using PIT tag recapture data, we were able to calculate a minimum fallback rate of steelhead at Tumwater Dam in 2010. Nearly all the steelhead (99.7\%) that migrated past Tumwater Dam were implanted with a PIT tag in the pelvic girdle. PIT tag detection at all Columbia and Snake River hydroelectric projects and some major spawning tributaries downstream of Tumwater

Dam (e.g., Peshastin Creek, Prosser Dam in the Yakima Basin) provided recapture data. Because some steelhead may have spawned in areas downstream of Tumwater Dam with no PIT tag antenna array (e.g., lower Wenatchee, Icicle, Mission, and Chumstick) or simply lost their tag, fallback rates were considered minimum values. Of the PIT tagged steelhead that were passed upstream of Tumwater Dam $(N=2,263), 1.3 \%(N=29)$ were detected prior to spawning downstream of Tumwater Dam. While most fallback steelhead ( $86 \%, N=25$ ) were detected at hydroelectric dams in the Columbia River upstream of the Wenatchee River, a small number of fish were also detected in Peshastin Creek $(N=4)$. We used estimates of prespawn mortality and observed fallback rates to adjust run escapement estimates upstream of Tumwater Dam that may better represent the actual size of the spawning population. After adjustment, the proportion of the run escapement accounted for on the spawning grounds increased from $66 \%$ to $82 \%$ (Table 5).

${ }^{\text {a }}$ Adjusted for a fallback rate of $8.0 \%$ as determined by PIT tag detections for the 2009 brood.
${ }^{\mathrm{b}}$ Adjusted for a fallback rate of $1.3 \%$ as determined by PIT tag detections for the 2010 brood.

## Steelhead Redd Life

Standard redd life averaged 27 d in the 2010, but exhibited similar high variation within each reach (CV $37-43$; Table 6). In all reaches, operational redd life (mean = 18 d ) was shorter than standard redd life ranging between $53-87 \%$ of the standard redd life. Standard redd life was significantly correlated with reach elevation ( $r=0.91, P<0.02$ ), but not operational redd life ( $r=0.19, P=0.72$ ). Potential factors that influenced redd life (e.g., environmental and habitat) will be evaluated at a later date.

Table 6. Summary results of steelhead redd life variability in the Wenatchee Basin in 2010.

| Reach | Mean | $N$ | SD | Range |  |  |  |  |  |
| :--- | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |

| N3 | 20.4 | 13 | 5 | 24.5 | 14 | 33 |  |  |  |

## Observer Efficiency Study

Of the six census reaches identified before spawning, one reach was not included in the analysis (Nason 1) because of low redd abundance. The redd abundance in Nason 1 reach was only 28 redds and well below the minimum sample size of 50 redds. Of those redds identified in Nason 1 reach, most were already not visible when independent surveys were to be conducted further reducing our sample size. Variation in the number of redds independent observers found within a census reach was large (CV range 29$77 \%$; Table 7). The mean proportion of visible redds correctly indentified within a reach was positively correlated with density $(r=0.98 ; P<0.005)$ and negatively correlated with stream width $(r=-0.80 ; P=0.10)$.

Table 7. Summary results of single pass steelhead redd observer variability surveys in the Wenatchee Basin in 2010.

| Census <br> reach | $N$ |  | Redd statistics |  |  | Redds |  | Omission |  |  |
| ---: | ---: | ---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  |  |  |  |  |  |  |  |  |  |  |
|  |  | Mean | CV | Range | $\%$ | SD | $\%$ | SD | $\%$ | SD |
| P1 | 9 | 16 | 38 | $3-24$ | 48.8 | 18.3 | 51.2 | 18.3 | 17.2 | 17.6 |
| N3 | 10 | 34 | 45 | $17-54$ | 61.2 | 16.2 | 38.8 | 16.2 | 14.0 | 11.3 |
| I1 | 10 | 24 | 29 | $12-36$ | 49.8 | 14.3 | 50.2 | 14.3 | 22.5 | 9.0 |
| W9 | 8 | 21 | 77 | $9-52$ | 30.9 | 22.3 | 69.1 | 22.3 | 40.6 | 11.7 |
| W10 | 11 | 34 | 40 | $18-61$ | 41.2 | 13.1 | 58.8 | 13.1 | 20.7 | 13.2 |

Individual surveyor observer efficiencies showed wide variation in correctly identifying steelhead redds with a range of $9.1 \%$ to $66 \%$ and a mean of $44.9 \%$ (Table 8). The
proportion of features that were incorrectly classified as steelhead redds (i.e., False ID) was also highly variable with a range of $0 \%$ to $45.1 \%$ and a mean of $22.3 \%$. The proportion of redds correctly identified by an independent observer among reaches was slightly lower and more variable ( mean $=0.43 ; \mathrm{CV}=41 \%$ ) than the variation within a reach (mean $=0.46 ; \mathrm{CV}=39 \%$ ).

Table 8. Summary of individual redd observer variability conducted during steelhead spawning ground surveys in the Wenatchee Basin.

| Surveyor <br> Aliases | $N$ | Redds |  | Omission |  | False ID |  |
| :---: | :---: | ---: | ---: | ---: | ---: | ---: | ---: |

| Q | 1 | 35.4 | - | 64.6 | - | 19.0 | - |
| R | 1 | 51.2 | - | 48.8 | - | 4.3 | - |
| S | 1 | 61.9 | - | 38.1 | - | 32.8 | - |
| Mean |  | 44.9 | 13.1 | 55.1 | 13.1 | 22.3 | 9.2 |

No relationship between experience conducting salmonid spawning ground surveys and the proportion of redds correctly $(r=0.06, P=0.66)$ or the falsely identified $(r=-0.05$, $P=0.73$ ) was found. When restricted to only steelhead spawning ground surveys, relationships improved slightly for both correct redds ( $r=0.19, P=0.19$ ) and false redds ( $r=-0.06, P=0.68$ ) but not statistically significant. However, prior experience conducting steelhead spawning ground surveys on a specific reach was significantly related to the proportion of correctly identified redds ( $r=32, P<0.03$; Figure 3), but not the proportion of redds falsely identified $(r=-0.22, P=0.13)$. We also found that as the proportion of redds correctly identified increased, the proportion of false redds decreased ( $r=-0.35, P<0.02$ ).

Figure 3. The relationship between the proportion of steelhead redds correctly identified and the surveyor's prior experience conducting steelhead surveys on a specific reach.

Because redd life is shorter than the spawning period, estimates of observer efficiency included only visible redds. Mean total error for redd observer efficiencies for visible redds was $67.1 \%(\mathrm{CV}=29.7)$ of all features identified (Figure 4). While net error was only $39.9 \% ~(\mathrm{CV}=58.2$ ), but more variable than total error (Figure 5). Total and net error rates based on the total number redds were $36.8 \%(C V=35.9)$ and $21.6 \%(C V=63.1)$, respectively (Figure 6 and 7). While error rates based on the total number of redds were lower than those based only on visible redds, in nearly all cases ( $92 \%$ ) redd abundance was underestimated (Figure 8 and 9). Interestingly, no relationship between total error rates (Figure 10) or net error rates (Figure 11) and the number of visible redds was detected.

Figure 4. Total error (\# of false redds + \# of redds omitted/\# of visible redds) by surveyor for Wenatchee steelhead spawning ground surveys in 2010.

Figure 5. Net error (\# of false redds - \# of redd omitted/\# of visible redds) by surveyor for Wenatchee steelhead spawning ground surveys in 2010.

Figure 6. Total error (\# of false redds + \# of redds omitted/\# of total redds) by surveyor for Wenatchee steelhead spawning ground surveys in 2010.

Figure 7. Net error (\# of false redds - \# of redd omitted/\# of total redds) by surveyor for Wenatchee steelhead spawning ground surveys in 2010.

Figure 8. Total error rates compared to net error rates of visible redds for ground based redd counts in census reaches for Wenatchee steelhead in 2010.

Figure 9. Total error rates compared to net error rates of the total number of redds for ground based redd counts in census reaches for Wenatchee steelhead in 2010.

Figure 10. Total error rates compared to the number of visible redds based on ground based redd counts in census reaches for Wenatchee steelhead in 2010.

Figure 11. Net error rates compared to the number of visible redds based on ground based redd counts in census reaches for Wenatchee steelhead in 2010.

At the reach scale, mean error rates were highly variable within a reach (Table 9).
However, mean error rates for tributaries were more similar than rates for Wenatchee River reaches. Mean error rates for tributaries were smaller but more variable than those for the Wenatchee River. Discharge was positively correlated with error rates (Figure 12). While redd density was negatively correlated (Figure 13). Error rates for visible redds was also significantly related to the error rates for all redds (Figure 14).

Table 9. Mean redd observer error rates for steelhead census reaches in Wenatchee Basin in 2010.

| Reach | Error rates for all redds |  |  |  | Error rates for visible redds |  |  |  |

## Steelhead Spawning Distribution and Timing

Of the 935 redds identified in 2010, females were observed on 232 ( $25 \%$ ). Of those, anchor tags were identified on 113 ( $49 \%$ ) females comprised of 42 wild and 71 hatchery steelhead. The majority of the anchor tag observations were on the upper Wenatchee River (55\%) and Nason Creek (40\%). Hence, the analysis of hatchery and wild spawning distribution and timing was limited to the specific reaches were the majority of the observations were made.

In the Wenatchee River, steelhead redds were observed throughout the entire river, but exhibited a clumped distribution skewed heavily to the upper reaches (Figure 15).
Tagged female steelhead were observed in the upper most reaches (W9 and W10) of the Wenatchee River (rkm 59-87), a section that contained $74 \%$ of all redds found in the Wenatchee River (Figure 16). No difference in spawning distribution of hatchery and naturally produced steelhead was detected in the upper Wenatchee River (t-test: $\mathrm{P}=0.24$ ) or in any reach of the upper Wenatchee River (ANOVA: $\mathrm{P}=0.40$ ). Spawn timing in the upper Wenatchee River was significantly influenced by elevation (Homogeneity of slopes model: elevation effect, $\mathrm{P}<0.02$ ). However, after accounting for elevation, no differences were found between hatchery and naturally produced steelhead (ANCOVA: Origin effect, $\mathrm{P}=0.76$; Figure 17).

The spawning distribution in Nason Creek was more uniform than in the Wenatchee River, but was still heavily skewed to the upper reaches ( N 2 and N 3 ) of the survey area (Figure 18). No difference in spawning distribution of hatchery and naturally produced fish was detected ( t -test: $\mathrm{P}=0.10$ ). Comparison by reach and parental origin (wild and hatchery [ W x W and unknown]) also resulted in no significant difference (ANOVA: origin x reach effect, $\mathrm{P}=0.83$; Figure 19). Because no other known hatchery fish ( $\mathrm{H} \times \mathrm{W}$ parental cross = green anchor tag) were observed in Nason Creek, we assumed that unknown hatchery fish were likely $\mathrm{W} \times \mathrm{W}$ fish that had lost their elastomer tag after release. Elevation did not significantly influence spawn timing in Nason Creek ( $\mathrm{P}=$ 0.67 ) presumably due to relatively low gradient of the survey reaches. Pooling data across reaches, no difference in spawn timing was detected ( t -test: $\mathrm{P}=0.90$ ).

## Discussion

Suboptimal survey conditions as a result of above normal river discharge during and following the peak of spawning likely decreased observer efficiency compared to previous years and may have resulted in an underestimate of redd abundance. Despite these factors, the proportion of the run escapement accounted for on the spawning grounds was much greater than expected. We attributed this increase to the increase in survey frequency. In previous years, index areas were surveyed approximately once a week. Female steelhead appear to have a relatively short redd residence time (1-3 d) compared to Chinook salmon (4-16 d). Hence, the probability of detecting a steelhead redd is likely greater when the redd is newly constructed and the female steelhead is still present on the redd. However, redd density was correlated to observer efficiency and may have contributed to a greater proportion of run escapement accounted for. In 2011, redd densities will be approximately $50 \%$ of 2010 and should provide more information on the influence of survey frequency.

High correlation between the expanded total redd counts and run escapement ( $r=0.93$ ) suggest that the methodology used to estimate spawner abundance can be very robust. It also suggests that factors responsible for the observed difference in run and estimated spawning escapement are relatively constant with respect to escapement levels across years. Given the large differences between run and spawn escapement upstream of Tumwater Dam, it is evident that multiple factors are contributing to the difference in the escapement estimates.

Tumwater Dam offers a unique opportunity to examine all the possible factors that may influence the size of the spawning population. Furthermore, it is not unreasonable to apply results of studies designed to answer these critical uncertainties to all populations in the upper Columbia River Basin. In the following section, we discuss these factors in more detail.

## Estimates of the Number of Redds

The current methodology does not involve conducting weekly surveys of the entire available spawning habitat (e.g., spring Chinook, summer Chinook, and sockeye). Steelhead are thought to have a greater range of spawning habitats than other anadromous species making a total redd census logistically impractical and costly. In the Wenatchee Basin, the Integrated Status and Effectiveness Monitoring Program (ISEMP) has been conducting probabilistic sampling (e.g., GRTS) of those areas not covered under the current methodology. When available, annual estimates of redd abundance outside of the current survey area should provide some indication regarding the extent of steelhead spawning habitat. Within the current survey area, while a majority of the steelhead redds are consistently found within index areas, this may simply be a result of an artifact in the methodology and river reaches surveyed. Furthermore, observer efficiency is potentially a large source of error in conducting redd counts (Dunham et al. 2001; Muhlfeld et al. 2006). Studies were conducted in 2010 to estimate observer efficiency and not only identify, but also quantify sources of error (redd omission or false identification). Other
studies are planned (i.e., 2011 and beyond) that are designed to evaluate the accuracy of the current spawning ground protocol.

## Spawning Escapement Estimates

Monitoring and evaluation plans require estimates of the spawning population in order to evaluate hatchery program effectiveness (e.g, wild and hatchery abundance and productivity) and determine appropriate escapement levels (i.e., carrying capacity). Steelhead exhibit a diverse life history and complex migration patterns thereby reducing the reliability that run escapement estimates (i.e., dam counts) accurately reflect the size of the spawning population. Steelhead spawning ground surveys are currently conducted in every major steelhead population in the Upper Columbia Basin. However, uncertainty in using these data to estimate the size of the spawning population lies in some factors previously discussed (i.e., observer efficiency and sampling design), but also in the manner in which redd counts are expanded to estimate the population.

The conversion of redd counts to an estimate of the spawning population requires knowledge of the average number of redds constructed per female and the number of fish per redd (Gallagher et al. 2007). In some populations, female steelhead were reported to construct multiple redds. If steelhead in the Wenatchee Basin do construct multiple redds, differences in run and escapement estimates would increase as a result of a lower spawning escapement estimate. For example, if female steelhead construct an average of 1.5 redds, the difference in run and spawning escapement estimates would increase $9 \%$. Redd abundance estimates are used to estimate the female escapement, which are then expanded by the sex ratio to estimate the male population on the spawning grounds. The number of fish per redd is based on the sex ratio of the population. Error associated with observer accuracy (i.e., gender misassignments) could be corrected using portable ultrasound devices. This approach assumes 1) equal survival to spawning and 2) every male spawns on average at one redd location. A tagging study is needed and planned in the next few years to test these assumptions.

## Observer Efficiency

The correct identification of steelhead redds in the Wenatchee Basin was higher in the tributaries of the Wenatchee River than the main stem itself. This could be directly related with the attributes of the tributaries versus the main stem Wenatchee River (i.e. redd density, stream depth, width and channel complexity). In addition, other factors that may contribute to observer efficiency include surveyor experience and environmental conditions (i.e. discharge, cloud cover, precipitation and turbidity). Given the wide range of individual observer efficiencies an attempt to quantify surveyor experience and channel complexity should be made. Observer efficiencies rates calculated using this method represent instantaneous observer efficiency rather than the efficiency of weekly or semi-weekly surveys to estimate redd abundance. Methods are being developed to estimate the variance of redd counts and should be finalized in 2012.

## Spawning Distribution and Timing

Differences in spawn timing have been observed in Wenatchee summer steelhead broodstock, but fish are held in a controlled environment on well water. Based on the differences observed in the hatchery, it is possible that a considerable portion of hatchery origin steelhead spawn prior to initiation of spawning ground surveys. Spawning ground surveys start in early March with redds typically being found during April suggesting that hatchery steelhead are spawning within the current survey period.

Results from 2010 suggest that hatchery and naturally produced fish do have similar spawning distributions, both spatially and temporally. Although the analysis was restricted to the upper Wenatchee River and Nason Creek, these areas comprise the majority of redds found upstream of Tumwater Dam. Similar studies planned for 2011 will provide an additional year of data.

## Recommendations

Of all the factors that are contributing to the difference between run and spawning escapement estimates, redds constructed in streams not included in the survey area have the potential to account for a significant portion of the observed difference. The reported number of redds upstream of Tumwater Dam underestimate the total number of redds because all available spawning habitat (i.e., low order streams) is not surveyed. Studies have been ongoing in the Wenatchee Basin designed to estimate the number of redds in areas not covered under the current survey design. Data from these studies (i.e., ISEMP) must be analyzed and incorporated into spawning escapement estimates.

The accuracy and precision of the current methodology used in estimating the redd abundance and observer efficiency are currently ongoing. Studies focused on testing assumptions used in estimating the size of the spawning population (number of redds per female and number of fish per redd) should incorporate an assessment of 1) fallback 2) survival to spawning 3) the spawning distribution of the hatchery and wild steelhead. Information from these studies is required to ensure spawning escapement estimates have sufficient accuracy and precision, such that inferences regarding the efficacy of naturally spawning hatchery steelhead can be made in a timely manner.

Spawning distributions of hatchery and wild steelhead in the Wenatchee Basin can be assessed at the tributary level using PIT tags. All major and minor spawning areas will eventually have instream PIT tag antenna arrays. However, this methodology requires that an adequate and representative sample of adults is tagged every year. Spawning distribution within tributaries at a reach level can also be assessed using instream arrays if desired. However, assessment of spawn timing in the natural environment is problematic and will require a periodic assessment of individuals on the spawning grounds.

Appendix D4. Steelhead spawning distribution in the Peshastin Creek Basin in 2010.

## APPENDIX E

NPDES Hatchery Effluent Monitoring, 2010

## NPDES MONITORING FOR WDFW FACILITIES.

All WDFW hatcheries monitor their discharge in accordance with the National Pollutant Discharge Elimination System (NPDES) permit. This permit is administered in Washington by the Washington Department of Ecology under agreement with the United States Environmental Protection Agency. The permit was renewed effective June 1, 2005 and will expire June 1, 2010.

Facilities are exempted from sampling during any month that pounds of fish on hand fall below $20,000 \mathrm{lbs}$ and pounds of feed used fall below $5,000 \mathrm{lbs}$, with the exception of offline settling basin discharges which are to be monitored once per month when ponds are in use and discharging to receiving waters.

Sampling at permitted facilities includes the following parameters:

| $<$ FLOW | Measured in millions of gallons per day (MGD) discharge. |
| :---: | :---: |
| $<$ SS EFF | Average net settleable solids in the hatchery effluent, measured |
| $<$ TSS COMP | Average net total suspended solids, composite sample ( $6 \mathrm{x} /$ day) of the hatchery effluent, measured in mg/L. |
| $<$ TSS MAX | Maximum daily net total suspended solids, composite sample (6 x/day) of the hatchery effluent, measured in $\mathrm{mg} / \mathrm{L}$. |
| <SS PA | Maximum settleable solids discharge from the pollution abatement pond, measured in $\mathrm{ml} / \mathrm{L}$. |
| <SS \% | Removal of settleable solids within the pollution abatement pond from inlet to outlet, measured as a percent. No longer required under permit effective June 1, 2000. |
| $<$ TSS PA | Maximum total suspended solids effluent grab from the pollution abatement pond discharge, measured in $\mathrm{mg} / \mathrm{L}$. |
| $<\mathrm{TSS}$ \% | Removal of suspended solids within the pollution abatement pond from inlet to outlet, measured as a percent. No longer required under permit effective June 1, 2000. |
| <SS DD | Settleable solids discharged during drawdown for fish release. One sample per pond drawdown, measured in $\mathrm{ml} / \mathrm{L}$. |
| $<$ TRC | Total residual chlorine discharge after rearing vessel disinfection and after neutralization with sodium thiosulfate. One sample per disinfection, measured in $\mathrm{ug} / \mathrm{L}$. |

In addition, at Similkameen Hatchery only, the following sampling was conducted at the request of WA Dept of Ecology, but is not required under NPDES permit:
$<$ SS IW Settleable solids influent grab taken as wastes are pumped into the pollution abatement pond, measured in $\mathrm{mg} / \mathrm{L}$.
$<$ TSS IW Total suspended solids influent grab as wastes are pumped into the pollution abatement pond, measured in $\mathrm{mg} / \mathrm{L}$.

National Pollutant Discharge Elimination System (NPDES) Effluent Summary
for the period of January 1, 2010 through December 31, 2010
as reported on the Discharge Monitoring Reports (DMRs)

## APPENDIX F

Steelhead Stock Assessment at Priest Rapids Dam, 2008-2009

## Priest Rapids Dam 2008-2009 Adult Upper Columbia River Steelhead Run-Cycle Stock Assessment Report

## Introduction

Upper Columbia River (UCR) steelhead stock assessment sampling at Priest Rapids Dam (PRD) is authorized through the Endangered Species Act (ESA) Section 10 Permit 1395 (NMFS 2003). Permit authorizations include interception and biological sampling of up to 10 percent of the UCR steelhead passing PRD to determine upriver population size, estimate hatchery to wild ratios, determine age class contribution and evaluate the need for managing hatchery steelhead consistent with ESA recovery objectives which include fully seeding spawning habitat with naturally produced UCR steelhead supplemented with artificially propagated enhancement steelhead (NMFS 2003).

## Stock Assessment

The 2008 steelhead sampling at Priest Rapids Dam began 10 July and concluded 16 October. Sampling consisted of operating the Priest Rapids Off Ladder Trap (OLAFT), located on the left bank Priest Rapids Dam, 8 hours per day, on Tuesdays and Thursdays, for a total of 32 sampling days. Steelhead were trapped, handled and released in accordance with Section 2.1 and 2.2.1 of the National Marine Fisheries Service (NMFS) Biological Opinion for ESA Permits 1395, 1396 and 1423 (NMFS 2003a). The cumulative sample rate attained during 2008 totaled $8.9 \%$ and no steelhead mortalities were observed.

The Washington Department of Fish and Wildlife (WDFW) sampled 1,454 steelhead of the 2008/2009 run-cycle passing PRD, totaling 16,558 steelhead, for an overall sampling rate of $8.9 \%$. Of the 1,454 steelhead sampled, $1,188(81.7 \%)$ were hatchery origin and 266 (18.3\%) were wild origin. The estimated 2008-2009 run- cycle total wild steelhead return was 3,030 representing $135.5 \%$ of the 1986-2007 average, $110.3 \%$ of the recent 5year average (Table 1).

Based on external marks, external and internal tags, 1,188 hatchery origin steelhead sampled at Priest Rapids Dam during the 2008 return cycle included, $24.7 \%$ Wenatchee hatchery-origin steelhead and 64.4\% "above Wells Dam" hatchery origin steelhead ${ }^{1 /}$ (Table 2)., while $8.9 \%$ of the hatchery origin steelhead sampled could not be assigned to a specific hatchery program. Ringold FH origin steelhead were not represented in the sample (Table 2).

| 2008 | 13,528 | 3,030 | 18.3 | 16,558 |
| 1986-2008 average | 10,357 | 2,270 | 18.0 | 12,627 |
| 2003-2008 average | 12,603 | 2,819 | 18.4 | 15,423 |

${ }^{1 /}$ A return cycle is the combined total of steelhead passing PRD from 1 June - 30 November during year ( x ), plus steelhead passing PRD between 15 April and 31 May on year ( $\mathrm{x}+1$ ).

Table 2. Origin classification of steelhead sampled at Priest Rapids Dam, 10 July - 16 October 2008.

Reconciliation of salt water age of wild and hatchery steelhead sampled at Priest Rapids Dam during 2008 was accomplished through scale sample analysis. Salt-age analysis of the 2008 UCR steelhead run-cycle provides an estimated hatchery-origin 1- salt and 2salt age composition of $48.3 \%, 51.7 \%$, respectively (Table 3). Natural origin steelhead salt ages were $62.0 \%$ and $38.0 \%$ for salt ages 1 and 2, respectively (Table 3).

Table 3. Salt-water age composition of 2008-2009 return cycle Upper Columbia River steelhead sampled at Priest Rapids Dam, corrected by scale age/origin determination.

## Origin

|  | Hatchery |  |  | Wild |  |  | Combined |  |
| :--- | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| Salt-age | $N$ | $\%$ |  | $N$ |  | $\%$ | $N$ | $\%$ |
| 1-salt | 351 | 48.3 |  | 168 | 62.0 |  | 519 | 52.3 |
| 2-salt | 376 | 51.7 |  | 97 | 38.0 |  | 473 | 47.7 |
| 3-salt | - | - |  | - | - |  | - | - |
| 4-salt | - | - |  | - | - |  | - | - |
| Total | $\mathbf{7 2 7}$ | $\mathbf{1 0 0}$ |  | $\mathbf{2 7 1}$ | $\mathbf{1 0 0}$ |  | $\mathbf{9 9 2}$ | $\mathbf{1 0 0}$ |

Freshwater residency of naturally produced Upper Columbia River steelhead present in the 2008-2009 run cycle were dominated by age-2 freshwater fish (71.4\%), and was marginally lower than the 1986-2007 average of $75.7 \%$ (Table 4).

Table 4. 2008 return year freshwater age of wild Upper Columbia River steelhead sampled at Priest Rapids Dam during steelhead stock assessment activities, compared to July - October 1986-2007 average.

| Freshwater age | $2007-2008$ run cycle |  |  | $1986-2007$ average |  |
| :--- | :---: | :---: | :--- | :---: | ---: |
|  | $N$ | $\%$ |  | $N$ | $\%$ |
| 1.x | 29 | 11.5 |  | 186 | 6.6 |
| 2.x | 180 | 71.4 |  | 2,126 | 75.7 |
| $3 . x$ | 42 | 16.7 |  | 475 | 17.0 |
| $4 . x$ | 1 | 0.4 |  | 18 | 0.6 |
| $5 . x$ | - | - |  | 2 | 0.1 |
| Total | $\mathbf{2 5 2}$ | $\mathbf{1 0 0}$ |  | $\mathbf{2 , 8 0 7}$ | $\mathbf{1 0 0}$ |

Wild and hatchery origin steelhead exhibited similar saltwater growth in the 2008 runcycle. Wild 1and 2-salt adults were slightly larger than their hatchery cohorts (Table 5). Age 1-salt hatchery and age 1 and 2-salt wild steelhead observed in the 2008-2009 adult run-cycle return past PRD were comparable in size to the 1986-2007 run-cycle average (Table 5).

Table 5. Average fork length of 1-salt and 2-salt, Upper Columbia River steelhead sampled at Priest Rapids Dam during July - October 2008 and the period between 19862007.

|  | Average fork length $(\mathrm{cm})$ |  |  |  |

|  | 2008-2009 run cycle |  |  |  |
| Salt age | Wild | Hatchery | 1986-2007 run cycle |  |
| x.1 | 60.5 | 58.8 | Wild | Hatchery |
| x.2 | 73.5 | 73.0 | 60.2 | 59.1 |

## APPENDIX G

Wenatchee Sockeye and Summer Chinook Spawning Ground Surveys, 2010

# PUBLIC UTILITY DISTRICT NUMBER 1 OF CHELAN COUNTY Natural Resource Division <br> Fish and Wildlife Department <br> 327 N. Wenatchee Ave., Wenatchee WA 98801 (509) 663-8121 

January 21, 2011
To: HCP Hatchery Committee
From: Joe Miller

Subject: 2010 Wenatchee River Basin Summer Chinook and Sockeye Salmon Spawning Ground Surveys

## Introduction

The Chelan County Public Utility District (District) has conducted or funded others to conduct intensive spawning ground surveys of spring and summer/fall (late run) ${ }^{1}$ Chinook salmon (Oncorhyncus tshawytscha) and sockeye salmon (O. nerka) in river basins of the Columbia River upstream of Rock Island Dam. Summer/fall Chinook spawn in the entire mainstem of the Wenatchee River, from the mouth to the lake (Figure 1; Table 1). Sockeye spawn in the White and Little Wenatchee River basins (Figure 2).

The spawning surveys are performed yearly to assist in evaluating the effectiveness of the District's hatchery program. The purpose of this document is to report the results of the 2010 Chinook and sockeye salmon spawning ground surveys in the Wenatchee River basin. Information included in this document describes abundance, distribution, and timing of spawning activity.

[^17]

Figure 1. Map of the Wenatchee River Basin with spawning and migrational areas of laterun (summer/fall Chinook) areas highlighted (copied from the Wenatchee Sub basin Plan, NWPCC 2004).

Figure 2. Map of the Wenatchee River Basin with spawning and migrational areas for sockeye highlighted (copied from the Wenatchee Sub basin Plan, NWPCC 2004).

## Methods

In 2010, the study methodology was the same as used in 2009. In 2008, the summer Chinook spawning surveys were modified to incorporate additional mapping index areas in all ten river reach strata. Additionally, summer Chinook naïve counts were also performed in all river reach strata by the Washington State Department of Fish and Wildlife (WDFW) and the District. Previously, mapping index counts focused on six of the ten reaches and naïve counts were conducted solely by WDFW.

## Chinook Spawning Ground Surveys

Chinook spawning ground surveys are conducted by foot, raft, or canoe. The most appropriate survey method is chosen for a given stream reach based on stream size, flow, and density of spawners. Because of the broad stream width and high spawner densities, individual summer Chinook redds are not flagged. Each reach is surveyed approximately once per week.

In 2010, summer Chinook spawning ground surveys occurred from September 20 to November 1.

Table 1: Designated survey reaches for spawning ground areas on the Wenatchee, Little Wenatchee, White, and Nepeequa rivers for all species.

| Survey Section | River Mile |
| :--- | :---: |
| Wenatchee River-Summer Chinook |  |
| Mouth to Sleepy Hollow Bridge | $0-3.5$ |
| Sleepy Hollow Bridge to Lower Cashmere Bridge | $3.5-9.5$ |
| Lower Cashmere Bridge to Dryden Dam | $9.5-17.5$ |
| Dryden Dam to Peshastin Bridge | $17.5-20.0$ |
| Peshastin Bridge to Leavenworth Bridge | $20.0-23.9$ |
| Leavenworth Bridge to Icicle Road Bridge | $23.9-26.4$ |
| Icicle Road Bridge to Tumwater Dam | $26.4-30.9$ |
| Tumwater Dam to Tumwater Bridge | $30.9-35.6$ |
| Tumwater Bridge to Chiwawa River | $35.6-48.4$ |
| Chiwawa River to Lake Wenatchee | $48.4-54.2$ |
|  | Little Wenatchee River-Sockeye |
| Mouth to Old Fish Weir | $0-2.7$ |
| Old Fish Weir to Lost Creek | $2.7-5.2$ |
| Lost Creek to Rainey Creek | $5.2-9.2$ |
| Rainey Creek to End | $9.2-$ End |
|  |  |
| Mouth to Sears Creek Bridge | $0-6.4$ |
| Sears Creek Bridge to Napeequa River | $6.4-11.0$ |
| Napeequa River to Grasshopper Meadows | $11.0-12.9$ |
| Grasshopper Meadows to Falls $\quad 12.9-14.3$ |  |
|  |  |
| Mouth to End | $0-$ End |

Peak and total redd count methodologies were used during the summer Chinook surveys in 2010 (see Appendix F of Murdoch and Peven (2005) for more detail). A peak count is conducted by counting all visible redds (new and old) observed within a reach on each survey. The objective of the peak redd count methodology is to capture the apex of spawning activity over an entire spawning season. This apex occurs at different times between reaches during the season, i.e. spawning begins sooner in the upstream reaches compared to the downstream reaches. The sum of all of the apex counts for the entire river is the peak redd count for the year. Peak counts provide an index of spawning and have been used historically (Attachment 1).

Two different approaches were used to estimate the total number of redds within the Wenatchee River. The first method used map counts to expand peak counts. Under this approach, a total redd count is conducted by counting or mapping only new or recently constructed redds within an area. Each new redd is mapped on aerial photos and enumerated. The objective of the total redd count methodology is to capture 1) "early" redds that may fade over time due to siltation or algae growth, and 2) redds that become disfigured by superimposition (when new redds are constructed on top of previously existing redds).

Since it is not feasible to map all new redds within the entire river, an expansion is used to estimate total count for the entire Wenatchee River. To account for the different spawning substrate types in the main stem Wenatchee River, the river was delineated into ten distinct reaches in consultation with WDFW (Table 2). Within each of these reaches, index areas have been identified as being representative areas of spawning activity. Peak counts are performed within each total reach (referred to as non-index areas), while mapping new redds only occurs within the index areas. An expansion is developed based on the ratio of mapped to peak counts for each reach (i.e., each reach has its own expansion factor), and the sum of the expanded counts is the estimate of the total redd counts. Additional details of how total redd counts are calculated are provided below.
a. Calculate an index peak expansion factor (IP) by dividing the peak number of redds in the index by the total number of redds (map count) in the index area.

$$
I P=n_{\text {peak }} / n_{\text {total }}
$$

b. Expand the non-index area peak redd counts by the $I P$ to estimate the total number of redds in the entire reach (reach total; $R T$ ).

$$
R T_{\text {peak }}=n_{\text {peak }} / I P
$$

c. Estimate the total number of redds (total redds; $T R$ ) by summing the reach totals.

$$
T R_{\text {peak }}=\sum R T
$$

The second approach relied on a "naïve" count to expand redd numbers in reaches that did not have map counts. As noted above, the reaches with map counts are referred to as index reaches and those that were not mapped are called non-index reaches. Near the end of the spawning period (early November), one team of observers counts all visible redds within all non-index reaches. A separate, independent team counts all visible redds within the index reaches (these are the naïve counts). Surveys within the index and non-index areas should occur within one day of each other near the end of the spawning period. The naïve counts are divided by the total map count to estimate an index expansion factor. This factor is then applied to the total visible count in the non-index areas to estimate the total number of redds within each reach. The sum of the expanded counts is the estimate of the total redd count for the river. Additional details of how total numbers of redds are estimated using this approach are provided below.
a. Calculate an index expansion factor (IF) by dividing the number of visible redds in the index by the total number of redds (map counts) in the index area.

$$
I F=n_{\text {visible }} / n_{\text {total }}
$$

b. Expand the non-index area redd counts by the proportion of visible redds in the index to estimate the total number of redds in the entire reach (reach total; $R T$ ).

$$
R T_{\text {visible }}=n_{\text {noor-indel }} / \text { IF }
$$

c. Estimate the total number of redds (total redds; $T R$ ) by summing the reach totals.

$$
T R_{\text {vistble }}=\sum R T
$$

The total redd count methods are believed to provide a more accurate indication of total spawning than the peak redd count methodology, because the peak count methodology only accounts for visible redds each week during the survey season. For example, summer Chinook redds that were visible during the first week of spawning may not be visible during the third week; those redds would be missed in the third and subsequent weeks' redd counts. Using the total count methodology, the redds in the first week would be mapped and accounted for in subsequent weeks, even though they may fade at some point during the future surveys.

Table 2: Index (Mapping) Areas on the Wenatchee River for 2010.

| Reach | Reach description | Distance <br> $(\mathrm{miles})$ | Mapping index area within reach |
| :---: | :--- | :---: | :--- |
| 1 | Sleepy Hollow Br to River Mouth | 3.5 | Sleepy Hollow Br to River Bend |
| 2 | Cashmere Br to Sleepy Hollow Br | 6 | Cashmere Br 2 to Old Monitor Br. |
| 3 | Dryden Dam to Cashmere Br | 8 | Dryden Dam to Williams Canyon |
| 4 | Peshastin Br to Dryden Dam | 2.5 | Peshastin Br to Dryden Dam |
| 5 | Leavenworth Br to Peshastin Br | 3.9 | Leavenworth Br to Irrigation Flume |
| 6 | Icicle Rd Br to Leavenworth Br | 2.5 | Icicle Mouth to Boat Takeout |
| 7 | Tumwater Dam to Icicle Rd Br | 4.5 | Penstock Br to Icicle Rd Br |
| 8 | Tumwater Br to Tumwater Dam | 4.7 | Tumwater Br to Swiftwater Campground |
| 9 | Old Plain Br to Tumwater Br | 12.8 | RR Tunnel to Swing Pool |
| 10 | Lake Wenatchee to Old Plain Br | 5.8 | Bridge to Swamp |

## Sockeye Spawning Abundance

In 2010, sockeye abundance was enumerated using two methods: (1) on-the-ground surveys utilizing an "area-under-the-curve" (AUC) approach, and (2) a PIT tag based mark recapture study.

## AUC Method:

Sockeye spawning ground surveys began August 24 and ended October 19. Spawning areas in the Little Wenatchee, Napeequa, and White rivers (Table 1) were surveyed at least once per week. Both the Little Wenatchee and White rivers have blocking falls, and spawning is known to occur only within the first few miles of the Napeequa River, a tributary to the White River.

The AUC method is based on the number of live spawners counted. Using AUC, the number of fish observed in a survey is plotted against the day of the year and the number of fish-days is estimated using an algorithm. The number of fish spawning is then estimated by dividing the cumulative fish-days by the estimated mean number of days that the average spawner is alive in the survey area (survey- or stream-life). This is then multiplied by a correction factor for fish visibility (observer efficiency; Hillborn et al. 1999).

Hillborn et al. (1999) outlined what they termed as the most commonly used form of AUC, trapezoidal approximation:

$$
\mathrm{AUC}=\sum_{\mathrm{i}=2}^{\mathrm{n}}\left(\mathrm{t}_{\mathrm{i}}-\mathrm{t}_{\mathrm{i}-1}\right) \frac{\left(\mathrm{x}_{\underline{i}}+\frac{\mathrm{x}_{\mathrm{i}-1}}{2}\right)}{2}
$$

where $t_{i}$ is the day of the year and $x_{i}$ is the number of salmon observed for the $i$ th survey. Attempts are often made to initiate surveys prior to the presence of fish; however, when
the first or last survey is not zero, then the above algorithm is not valid and Hillborn et al. (1999) recommend using the "rules" that the Alaska Department of Fish and Game use:

$$
\mathrm{AUC}_{\text {first }}=\frac{x_{i} \underline{S}}{2}
$$

where $s$ is the survey life. Attempts should also be made until all salmon die, but when this is not possible, then the final survey should be calculated:

$$
\mathrm{AUC}_{\text {last }}=\frac{x_{\text {last }} \underline{S}}{2}
$$

Then total escapement $(E)$ is estimated:

$$
\mathrm{E}^{\wedge}=\frac{\mathrm{AUC}}{s} v
$$

where v is a correction for observer efficiency. Since survey life has not been empirically estimated for the Wenatchee system, we used 11 days based on Perrin and Irvine (1990) and Hyatt et al. (2006).

## Mark Recapture Method:

Adult sockeye salmon were removed from the adult fishway at Tumwater Dam on the Wenatchee River, northwest of Leavenworth, Washington during the 2009 and 2010 migration. Fish were anesthetized, tagged with a PIT, and released into the forebay consistent with techniques used by the Washington Department of Fish and Wildlife. Resulting tag files were queried in PITAGIS (2010), providing detection histories for each study fish. Adult sockeye salmon were tagged at Bonneville Dam by another organization in 2009 and 2010; fish from this tag group that were detected at Tumwater Dam were also used in the analyses. Total passage of adult sockeye salmon through Tumwater Dam were obtained from Columbia River Data Access in Real Time (DART 2010).

Detection efficiency of in-stream arrays was calculated for the Little Wenatchee River in both 2009 and 2010; efficiency was calculated for the White River arrays after the 2010 migration since only a single array was available during 2009. The in-stream arrays include a series of upstream and downstream coils (i.e., Figure ). Combined, these coils represented the upstream and downstream detection arrays, respectively. Overall detection efficiency $P_{\text {all }}$ of the arrays was calculated based on observed detection probabilities of individual arrays:

$$
P_{\text {all }}=1-\left(1-P_{\text {array }_{1}}\right)\left(1-P_{\text {array } 2}\right)
$$

where the probability of missing a fish on both the upstream $P_{\text {array } 1}$ and downstream $P_{\text {array } 2}$ arrays are combined for an overall efficiency $P_{\text {all }}$ (Connolly et al. 2008).

Figure 3. PIT array configuration on the Little Wenatchee River, 2009.
Resulting data from passage at Tumwater Dam, mark and recapture using PITs, and detection efficiency estimates can provide estimation of escapement to spawning tributaries. Basic assumptions include: (1) the study population is "closed," i.e., no individuals die or emigrate between the initial mark and subsequent recaptures; (2) tags are not lost and detections are correctly identified; (3) all individuals have the same probability of being detected, and (4) the number of recapture events are proportional to the total population. Lastly, it is assumed that PIT-tagging efforts at Tumwater have negligible influence on fish behavior and tagged individuals behave similarly to untagged individuals. The resulting escapement rate, adjusted for detection efficiency, can then be applied to the total population as such:

$$
\text { Escapement }=\left(\frac{\left(\frac{O b s_{L W N}}{E f f_{L W N}}+\frac{O b s_{W T L}}{E f f_{W T L}}\right)}{P I T s_{T U M}}\right) \times \text { Counts }_{T U M}
$$

where the PIT detections (Obs) at the Little Wenatchee ( $L W N$ ) and lower White River ( $W T L$ ) are adjusted for detection efficiency ( $E f f$ ) at both sites, compared to the number released (PITs) at Tumwater Dam (TUM), and the resulting proportion is applied to the population observed (Counts) passing Tumwater Dam.

## Results

## Summer Chinook

## Peak Counts

The cumulative peak summer Chinook redd count was 2,553 in 2010, based on District ground surveys along the Wenatchee River (Table 3). Spawning activity began the last week of September and peaked during middle of October.

Table 3. Summary of summer Chinook redd peak counts, total redd estimates (TR) and spawner densities by reach in the Wenatchee River, 2010. Expansion factors were rounded to two decimal places $(\mathbf{0 . 0 0})$ prior to calculating reach totals.

| Reach | Peak Count | CCPUD Estimates |  | WDFW Estimates |  |
| :---: | :---: | :---: | :---: | :---: | :---: |
|  |  | $\mathbf{R T}_{\text {Peak }}$ | Density ${ }_{\text {Peak }}$ (redds/mile) | $\mathbf{R T} \mathrm{V}_{\text {Visible }}$ | Density $_{\text {Visible }}$ (redds/mile) |
| 1 | 12 | 18 | 5 | 18 | 5 |
| 2 | 129 | 183 | 30 | 111 | 18 |
| 3 | 184 | 230 | 29 | 463 | 58 |
| 4 | 58 | 77 | 31 | 153 | 61 |
| 5 | 76 | 111 | 28 | 87 | 22 |
| 6 | 1047 | 1426 | 570 | 1394 | 558 |
| 7 | 249 | 268 | 60 | 221 | 49 |
| 8 | 86 | 101 | 21 | 100 | 21 |
| 9 | 341 | 431 | 34 | 562 | 44 |
| 10 | 371 | 397 | 68 | 610 | 105 |
| Total | 2,553 | 3,242 | 60 | 3,719 | 69 |

## Total Counts

The total number of redds in the Wenatchee River was 3,242 ( $R T_{\text {peak }}$ ), using data from District surveys and the peak expansion factor. WDFW estimated 3,719 redds ( $R T_{\text {visble }}$ ) based on their naïve surveys (Table 3). All survey methods (peak and visible) indicated that redd densities were highest in Reach 6 and lowest in Reach 1 (Table 3; Figure 4), consistent with the previous three years. The historical summer Chinook peak counts (1996-2010) for the Wenatchee River basin are summarized in Attachment 1.

Figure 4. Alternative estimates of reach totals (RT) for summer Chinook redds in the Wenatchee River in 2010 [ $R T_{\text {peak }}=$ District peak counts expanded by peak expansion method and $\boldsymbol{R} T_{\text {visble }}(W D F W)=W D F W$ naïve counts expanded by naïve expansion factor].

## Sockeye AUC Method

Live fish counts
Fish counts were conducted for sockeye from August 24 through October 19. Peak spawning occurred in the Little Wenatchee (1,762); Napeequa River (321); and White River $(11,059)$ during the middle of September (Figure 5; Table 4).

Escapement
The total estimated spawning escapement of sockeye to the Wenatchee tributaries was 21,700 in 2010 (Table 4). The escapement estimate is based solely on tributary observations and does not include fish harvested in the Lake Wenatchee sockeye fishery.

Figure 5. Approximate live counts and survey dates for sockeye salmon in the Wenatchee River Basin, 2010.

Table 4. Number of live fish and total spawning escapement estimates for sockeye salmon in the Wenatchee Basin, August through October, 2010.

| River | Peak number of live fish | Escapement |
| :---: | :---: | :---: |
| Little Wenatchee | $\mathbf{1 , 7 6 2}$ | 2,543 |
| Napeequa | 321 | $\mathbf{4 7 0}$ |
| White | $\mathbf{1 1 , 0 5 9}$ | $\mathbf{1 8 , 6 8 7}$ |
| Total | 13,142 | 21,700 |

## Sockeye Mark Recapture Method

Fishway enumeration at Tumwater Dam indicated that 16,034 and 35,821 adult sockeye salmon passed the facility during the 2009 and 2010 migrations, respectively. The recreational harvest removed an estimated 2,229 and 4,129 fish during the two years, respectively, although anglers were requested to released marked fish. PIT tags were implanted in 1,085 and 1,164 (Table 5) of these fish prior to subsequent detections in nearby tributaries. Based on the recapture of PIT-tagged adult sockeye and assigned detection efficiencies, total estimated escapement from Tumwater Dam to the White and Little Wenatchee rivers was 14,452 in 2009, including 13,876 fish in the White River and 576 fish in the Little Wenatchee River (Table 6). Estimated escapement in 2010 totaled 21,604, including 19,542 fish in the White River and 2,062 fish in the Little Wenatchee River (Table 6). Combined escapement rates represented 0.901 of the population in 2009, and 0.603 in 2010 (Table 6).

Table 5. Number of adult sockeye salmon PIT-tagged, released, and detected upstream of Tumwater Dam in 2009 and 2010, including escapement estimates of PIT-tagged fish based on array detection probabilities.

## Executive Summary

Nine spawning populations of sockeye (Oncorhynchus nerka) salmon have been identified in Washington, including stocks in the Lake Wenatchee basin (SaSI 5800) (Washington Department of Fisheries et al. 1993). Lake Wenatchee sockeye are classified as an Evolutionary Significant Unit (ESU), and consists of sockeye salmon that spawn primarily in tributaries above Lake Wenatchee (the White River, Napeequa River, and Little Wenatchee Rivers). Since 1990, the Wenatchee Sockeye Program has released juveniles into Lake Wenatchee to supplement natural production of sockeye salmon in the basin. The program's broodstock are predominantly natural-origin sockeye adults returning to the Wenatchee River captured at Tumwater Dam (Rkm 52.0), where a netpen system is used to house both maturing adults and juveniles prior to release into Lake Wenatchee to over-winter.

Previous genetic studies have generally found a lack of concordance between population genetic relationships and their geographic distributions. These studies indicate that the nearest geographic neighbors of sockeye salmon populations are not necessarily the most genetically similar. Specifically for the Columbia River Basin, sockeye from Lake Wenatchee, Okanogan River, and Redfish Lake may be more closely related to a population from outside the Columbia River (depending on marker used) then to each other.

In this study we investigated the temporal and spatial genetic structure of Lake Wenatchee sockeye collections, without regard to sockeye populations outside of the Lake Wenatchee area. Our primary objective here was to determine if the Wenatchee Sockeye Program affected the natural Lake Wenatchee sockeye population. More specifically, we were tasked to determine if the genetic composition of Lake Wenatchee sockeye population had been altered by a supplementation program that was based on the artificial propagation of a small subset of that population. Using microsatellite DNA allele frequencies, we investigated population differentiation between temporally replicated collections of natural-origin Lake Wenatchee sockeye and program broodstock. We analyzed thirteen collections of Lake Wenatchee sockeye (Table 1), eight temporally replicated collections of natural-origin Lake Wenatchee sockeye ( $\mathrm{N}=786$ ) and five temporally replicated collections of Wenatchee Sockeye Program broodstock ( $\mathrm{N}=248$ ). Paired natural - broodstock collections were available from years 2000, 2001, 2004, 2006, and 2007.

## Conclusions

We observed that allele frequency distributions were consistent over time, irrespective of collection origin, resulting in small and statistically insignificant measures of genetic differentiation among collections. We interpreted these results to indicate no year-to-year differences in allele frequencies among natural-origin or broodstock collections.
Furthermore, there were no observed difference between pre- and post-supplementation collections. Therefore, we accepted our null hypothesis that the allele frequencies of the broodstock collections equaled the allele frequencies of the natural collections, which
equaled the allele frequency of the donor population. Given the small differences in genetic composition among collections, the genetic model for estimating $\mathrm{N}_{\mathrm{e}}$ produced estimates with extremely large variances, preventing the observation of any trend in $\mathrm{N}_{\mathrm{e}}$.

## Introduction

A report titled "Conceptual Approach to Monitoring and Evaluating the Chelan County Public Utility District Hatchery Programs" was prepared July 2005 by Andrew Murdoch and Chuck Peven for the Chelan PUD Habitat Conservation Plan's Hatchery Committee. This report outlined 10 objectives to be applied to various species assessing the impact (positive or negative) of hatchery operations mitigating the operation of Rock Island Dam. This current study pertains only to Lake Wenatchee sockeye and objective 3:

> Determine if genetic diversity, population structure, and effective population size have changed in natural spawning populations as a result of the hatchery program. Additionally, determine if hatchery programs have caused changes in phenotypic characteristics of natural populations.

In order to evaluate cause and effect of hatchery supplementation, WDFW Molecular Genetics Lab surveyed genetic variation of Lake Wenatchee sockeye. The conceptual approach for this project follows that of a parallel study regarding the Wenatchee River spring Chinook supplementation program (Blankenship et al. 2007). We determined the genetic diversity present in the Lake Wenatchee sockeye population by analyzing temporally replicated collections spanning 1989-2007, which included collections from before and following the inception of the Wenatchee Sockeye Program. Documenting the genetic composition of the Lake Wenatchee sockeye population is necessary to assess the effect of the hatchery program on the Lake Wenatchee population. In addition, this work provides a genetic baseline for future projects requiring genetic data. See study objectives below for specific details about how this project addresses Murdoch and Peven (2005) objective 3.

## Lake Wenatchee Sockeye Salmon

Nine spawning populations of sockeye (Oncorhynchus nerka) salmon have been identified in Washington (Washington Department of Fisheries et al. 1993): 1) Baker

River, 2) Ozette Lake, 3) Lake Pleasant, 4) Quinault Lake, and 5) Okanogan River (classified as native stock); 6) Cedar River (classified as non-native stock); 7) Lake Wenatchee, classified as mixed stock); 8) Lake Washington/Lake Sammamish tributaries; and 9) Lake Washington beach spawners (classified as unknown origin). Chapman et al. (1995) listed four additional spawning aggregations of sockeye salmon that appear consistently in Columbia River tributaries: the Methow, Entiat, and Similkameen Rivers; and Icicle Creek in the Wenatchee River drainage.

Located in north central Washington, the Wenatchee River basin drains a portion of the eastern slope of the Cascade Mountains, including high mountainous regions of the Cascade crest. The headwater area of the Wenatchee River is Lake Wenatchee, a typical low productivity oligotrophic or ultra-oligotrophic sockeye salmon nursery lake (Allen and Meekin 1980, Mullan 1986, Chapman et al. 1995). Sockeye salmon bound for Lake Wenatchee enter the Columbia River in April and May and arrive at Lake Wenatchee in late July to early August (Chapman et al. 1995; Washington Department of Fisheries et al. 1993). The run timing of Lake Wenatchee sockeye salmon, classified as an Evolutionary Significant Unit (ESU), appears to have become earlier by 6-30 days during the past 70 years (Chapman et al. 1995; Quinn and Adams 1996). Additionally, scale pattern analysis suggests Wenatchee sockeye migrate past Bonneville Dam earlier than the sockeye bound for the Okanogan River (Fryer and Schwartzberg 1994). The Wenatchee population spawns from mid-September through October in the Little Wenatchee, White, and Napeequa Rivers above Lake Wenatchee (Washington Department of Fisheries et al. 1993), peaking in late September (Chapman et al. 1995). Limited beach spawning is believed to occur in Lake Wenatchee (L. Lavoy pers. com.; Mullan 1986), although Gangmark and Fulton (1952) reported two lakeshore seepage areas in Lake Wenatchee that were used by spawning sockeye salmon. Sockeye salmon fry enter Lake Wenatchee between March and May (Dawson et al. 1973), and typically rear in the lake for one year before leaving as smolts (Gustafson et al. 1997; Peven 1987).

Both the physical properties of the habitat and ecological/biological factors of the sockeye populations differ between the Lake Wenatchee ESU and the geographically
proximate Okanogan ESU. For example: 1) Different limnology is encountered by sockeye salmon in Lakes Wenatchee and Osoyoos; 2) Lake Wenatchee sockeye predominantly return at ages four and five (a near absence of 3-year-olds), where a large percentage of 3-year-olds return to the Okanogan population; and 3) the apparent one month separation in juvenile outmigration-timing between Okanogan- and Wenatcheeorigin fish (Gustafson et al. 1997 and references therein).

## Sockeye Artificial Propagation In Lake Wenatchee

The construction of Grand Coulee Dam completely blocked fish passage to the upper Columbia River, and $85 \%$ of sockeye salmon passing Rock Island Dam between 1935 and 1936 were estimated to be from natural stocks bound for areas up-river to Grand Coulee Dam (Mullan 1986; Washington Department of Fisheries et al. 1938). To compensate for loss of habitat resulting from Grand Coulee Dam, the federal government initiated the Grand Coulee Fish-Maintenance Project (GCFMP) in 1939 to maintain fish runs in the Columbia River above Rock Island Dam. Between 1939 and 1943, all sockeye salmon entering the mid-Columbia River were trapped at Rock Island Dam, and over 32,000 mixed Lake Wenatchee, Okanogan River, and Arrow Lake adult sockeye salmon were released into Lake Wenatchee (Gustafson et al. 1997 Appendix Table D-2). In addition to adult relocation, between 1941 and 1969 over 52.8 million fry descended from original spawners collected at Rock Island and Bonneville Dams, were released into Lake Wenatchee (Gustafson et al. 1997 Appendix Table D-2).

No releases of artificially-reared sockeye salmon occurred in the Wenatchee watershed during the years 1970 to 1989 (Gustafson et al. 1997 Appendix Table D-2). Since 1990, the Wenatchee Sockeye Program has released juveniles into Lake Wenatchee to supplement natural production of sockeye salmon in the basin. Sockeye adults returning to the Wenatchee River are captured at Tumwater Dam (Rkm 52.0) and transferred to Lake Wenatchee net pens until mature. The Wenatchee Sockeye Program goals are 260 adults with an equal sex ratio, $<10 \%$ hatchery-origin returns (identified by coded wire tags), and the adults removed for broodstock account for $<10 \%$ of the run size. Fish are spawned at Lake Wenatchee and their gametes are taken to Rock Island Fish Hatchery

Complex (i.e., Eastbank) for fertilization and incubation. Fry are returned to the Lake Wenatchee net -pens after they are large enough to be coded wire tagged, and are housed in the pens until fall (one year after spawning), when they are liberated into the lake to over-winter. For brood years 1991 - 2004 an average of 218,683 (std. dev. $=71,090$ ) pen-reared Lake Wenatchee-origin juvenile sockeye salmon have been released yearly into Lake Wenatchee.

## Previous Genetic Studies

Protein (allozyme) variation - Surveying genetic variation at 12 allozyme loci, Utter et al. (1984) reported moderate population structure among 16 sockeye collections from southeast Alaska through the Columbia River Basin, including Okanogan and Wenatchee stocks, with an apparent genetic association between upper Fraser River and Columbia River sockeye salmon. Winans et al. (1996) surveyed variation at 55 allozyme loci for 25 sockeye salmon and two kokanee collections from 21 sites in Washington, Idaho, and British Columbia, and reported the lowest level of allozyme variability of any species of Pacific salmon and a highest level of inter-population differentiation. Furthermore, these authors reported that there was no clear relationship between geographic and genetic differentiation among the populations within there study. Other studies corroborate the results of Winans et al. (1996), finding a lack of discernible geographic patterning for sockeye salmon populations in British Columbia, Alaska, and Kamchatka (Varnavskaya et al. 1994, Wood et al. 1994, Wood 1995). These studies indicate that the nearest geographic neighbors of sockeye salmon populations are not necessarily the most genetically similar, which contrasts with the other Pacific salmon species that exhibit concordance between geographic and genetic differentiation (Utter et al. 1989, Winans et al. 1994, Shaklee et al. 1991). As part of the comprehensive status review of west coast sockeye salmon (Gustafson et al. 1997), NMFS biologists collected new allozyme genetic information for 17 sockeye salmon populations and one kokanee population in Washington and combined these data for analysis with the existing Pacific Northwest sockeye salmon and kokanee data from Winans et al. (1996). Results of the updated study were consistent with Winans et al. (1996), with no clear concordance between geographic and genetic distances. Sockeye salmon from Lake Wenatchee, Redfish Lake,

Ozette Lake, and Lake Pleasant are very distinct from other collections in the study, and Columbia River populations were not necessarily most closely related to each other. Gustafson et al. (1997) also examined between-year variability within a collection location and found low levels of statistical significance among the five Lake Wenatchee collections included in the study (For 10 pair-wise comparisons using sum-G test, five were statistically significant). Lake Wenatchee brood year 1987 accounted for three of the significant comparisons, which were driven by unusually high frequencies of two allozyme alleles (ALAT*95 and ALAT*108) (Winans et al. 1996). Nevertheless, Gustafson et al. (1997) conclude that, in general, temporal variation at a locale was considerably less than between-locale variation.

Nucleic acid variation - Beacham et al. (1995) reported levels of variation in nuclear DNA of $O$. nerka using minisatellite probes. They analyzed 10 collections, including a sample from Lake Wenatchee. Cluster analysis showed the Lake Wenatchee sample was different from all the other collections, including those from the Columbia River. Using a similar molecular technique, Thorgaard et al. (1995) examined the use of multi-locus DNA fingerprinting (i.e., banding patterns) to discriminate among 14 sockeye salmon and kokanee populations. Dendrograms based on analysis of banding patterns produced different genetic affinity groups depending on the probes used. While none of the five DNA probes showed a close relationship between Lake Wenatchee and Okanogan River sockeye salmon, if information from all probes were combined, $O$. nerka from Redfish Lake, Wenatchee, and Okanogan were separate from kokanee of Oregon and Idaho and a sockeye salmon sample from the mid-Fraser River.

## Study Objective

We documented temporal variation in genetic diversity (i.e., heterozygosity and allelic diversity), and investigated population differentiation between temporally replicated collections of natural-origin Lake Wenatchee sockeye and program broodstock, using microsatellite DNA allele frequencies. Temporally replicated collections from the same location can also be used to estimate effective population size $\left(\mathrm{N}_{\mathrm{e}}\right)$. If populations are "ideal", the census size of a population is equal to the "genetic size" of the population.

Yet, numerous factors lower the "genetic size" below census, such as, non-equal sex ratios, changes in population size, and variance in the numbers of offspring produced from parent pairs. $\mathrm{N}_{\mathrm{e}}$ is thought to be between 0.10 and 0.33 of the estimated census size (Bartley et al. 1992; RS Waples pers. comm.), although numerous observations differ from this general rule. $\mathrm{N}_{\mathrm{e}}$ can be calculated directly from demographic data, or inferred from observed differences in genetic variance over time. Essentially, when calculated from genetic data, $\mathrm{N}_{\mathrm{e}}$ is the estimated size of an "ideal" population that accounts for the genetic diversity changes observed, irrespective of abundance.

We will address the hypotheses associated with Objective 3 in Murdock and Peven (2005) using the following four specific tasks:

Task 1 - Document the observed genetic diversity.
Task 2 - Test for population differentiation among Lake Wenatchee collections and the associated supplementation program.

Task 2 was designed to address two hypotheses listed as part of Objective 3 in Murdoch and Peven (2005):

- Ho: Allele frequency Hatchery $=$ Allele frequency ${ }_{\text {Naturally produced }}=$ Allele frequency $_{\text {Donor pop }}$.
- Ho: Genetic distance between subpopulations Year $x={\text { Genetic distance between subpopulations }{ }_{\text {Year }} \mathrm{y}}^{\text {b }}$ Murdoch and Peven (2005) proposed these two hypotheses to help evaluate supplementation programs through a "Conceptual Process" (Figure 5 in Murdoch and Peven 2005). There are two components to the first hypothesis, which must be considered separately for Lake Wenatchee sockeye. The first component involves comparisons between natural-origin populations from Lake Wenatchee to determine if there have been changes in allele frequencies through time starting with the donor population. Documenting a change does not necessarily indicate that the supplementation program has directly affected the natural-origin fish, as additional tests would be necessary to support that hypothesis. The intent of the second component is to determine if the hatchery produced populations have the same genetic composition as the naturally produced populations.

Task 3 - Calculate $\mathrm{N}_{\mathrm{e}}$ using the temporal method for multiple samples from the same location to document trend.

Task 4 - Compare $\mathrm{N}_{\mathrm{e}}$ estimates with trend in census size for Lake Wenatchee sockeye.

## Methods and Materials

## Sampling

Thirteen collections of Lake Wenatchee sockeye were analyzed, eight temporally replicated collections of natural Lake Wenatchee sockeye ( $\mathrm{N}=786$ ) and five temporally replicated collections of Wenatchee Sockeye Program broodstock ( $\mathrm{N}=248$ ) (Table 1). Paired natural - broodstock collections were available from years 2000, 2001, 2004, 2006, and 2007 (Table 1). All collections were made at Tumwater Dam on the Wenatchee River. Note that collections classified as broodstock were predominantly natural-origin sockeye. A majority of the genetic samples were from dried scales. The tissue collections from 2006 and 2007 were fin clips stored immediately in ethanol after collection. DNA was extracted from stored tissue using Nucleospin 96 Tissue following the manufacturer's standard protocol (Macherey-Nagel, Easton, PA, U.S.A.).

## Laboratory Analysis

Polymerase chain reaction (PCR) amplification was performed using 17 fluorescently end-labeled microsatellite marker loci, One 2 (Scribner et al 1996) One 100, 101, 102, 105, 108, 110, 114, and 115 (Olsen et al. 2000), Omm 1130, 1135, 1139, 1142, 1070, and 1085 (Rexroad et al. 2001), Ots 3M (Banks et al. 1999) and Ots 103 (Small et al. 1998). PCR reaction volumes were $10 \mu \mathrm{~L}$, with the reaction variables being $2 \mu \mathrm{~L} 5 \mathrm{x}$ PCR buffer (Promega), $0.6 \mu \mathrm{~L} \mathrm{MgCl}_{2}(1.5 \mathrm{mM})$ (Promega), $0.2 \mu \mathrm{~L} 10 \mathrm{mM}$ dNTP mix (Promega), and $0.1 \mu \mathrm{~L}$ Go Taq DNA polymerase (Promega). Loci were amplified as part of multiplexed sets, so primer molarities and annealing temperatures varied. Multiplex one had an annealing temperature of $55^{\circ} \mathrm{C}$, and used 0.09 Molar (M) One 108, 0.06 M One 110, and 0.11 M One 100. Multiplex two had an annealing temperature of $53^{\circ} \mathrm{C}$, and used 0.08 M One 102, 0.1 M One 114, and 0.05 M One 115. Multiplex three had an annealing temperature of $55^{\circ} \mathrm{C}$, and used 0.08 M One 105 and 0.07 M Ots 103. Multiplex four had
an annealing temperature of $53^{\circ} \mathrm{C}$, and used 0.09 M Omm 1135 and 0.08 M Omm 1139. Multiplex five had an annealing temperature of $60^{\circ} \mathrm{C}$, and used $0.2 \mathrm{M} \mathrm{Omm} 1085,0.09 \mathrm{M}$ Omm 1070, and 0.05 M Ots 3M. Multiplex six had an annealing temperature of $48^{\circ} \mathrm{C}$, and used 0.06 M One 2, $0.08 \mathrm{M} \mathrm{Omm} \mathrm{1142}$,and 0.08 M Omm 1130. One 101 was run in isolation with a primer molarity of 0.06 . Thermal cycling was conducted on either PTC200 (MJ Research) or GeneAmp 9700 thermal cyclers as follows: $94^{\circ} \mathrm{C}$ ( 2 min ); 30 cycles of $94^{\circ} \mathrm{C}$ for $15 \mathrm{sec} ., 30 \mathrm{sec}$. annealing, and $72^{\circ} \mathrm{C}$ for 1 min .; a final $72^{\circ} \mathrm{C}$ extension and then a $10^{\circ} \mathrm{C}$ hold. PCR products were visualized by denaturing polyacrylamide gel electrophoresis on an ABI 3730 automated capillary analyzer (Applied Biosystems). Fragment analysis was completed using GeneMapper 3.7 (Applied Biosystems).

## Genetic data analysis

Assessing within collection genetic diversity - Heterozygosity measurements were reported using Nei's (1987) unbiased gene diversity formula (i.e., expected heterozygosity) and Hedrick's (1983) formula for observed heterozygosity. Both tests were implemented using the microsatellite toolkit (Park 2001). For each locus and collection FSTAT version 2.9.3.2 (Goudet 1995) was used to assess Hardy-Weinberg equilibrium, where deviations from the neutral expectation of random associations among alleles were calculated using a randomization procedure. Alleles were randomized among individuals within collections (4160 randomizations for this dataset) and the $\mathrm{F}_{\text {IS }}$ (Weir and Cockerham 1984) calculated for the randomized datasets were compared to the observed $\mathrm{F}_{\text {IS }}$ to obtain an unbiased estimation of the probability that the null hypothesis was true. The 5\% nominal level of statistical significance was adjusted for multiple tests (Rice 1989). Genotypic linkage disequilibrium was calculated following Weir (1979) using GENETIX version 4.05 (Belkhir et al. 1996). Statistical significance of linkage disequilibrium results was assessed using a permutation procedure implemented in GENETIX for each locus by locus combination within each collection.

Assessing among collection genetic differentiation - The temporal stability of allele frequencies was assessed by the randomization chi-square test implemented in FSTAT version 2.9.3.2 (Goudet 1995). Multi-locus genotypes were randomized between
collections. The G-statistic for observed data was compared to G-statistic distributions from randomized datasets (i.e., null distribution of no differentiation between collections). Population differentiation was also investigated using pairwise estimates of $\mathrm{F}_{\text {ST }}$. Multi-locus estimates of pairwise $\mathrm{F}_{\mathrm{ST}}$, estimated by a "weighted" analysis of variance (Weir and Cockerham, 1984), were calculated using GENETIX version 4.05 (Belkhir et al.1996). $\mathrm{F}_{\text {ST }}$ was used to quantify population structure, the deviation from statistical expectations (i.e., excess homozygosity) due to non-random mating between populations. To determine if the observed $\mathrm{F}_{\mathrm{ST}}$ estimate was consistent with statistically expectations of no population structure, a permutation test was implemented in GENETIX (1000 permutations).

Effective population size $\left(\mathbf{N}_{\mathbf{e}}\right)$ - Estimates of the effective population size were obtained using a multi-collection temporal method (Waples 1990a). The temporal method assumes that cohorts are used, but we did not decompose the collection year samples into their respective cohorts using age data. Therefore, $\mathrm{N}_{\mathrm{e}}$ estimates that pertain to individual year classes of breeders are not valid; however the harmonic mean over all samples will estimate an $\mathrm{N}_{\mathrm{e}}$ that pertains to the time period from which the collections are derived. Comparing samples from years $i$ and $j$, Waples’ (1990a) temporal method estimates the effective number of breeders ( $\hat{\mathrm{N}}_{\mathrm{b}(\mathrm{i}, \mathrm{j})}$ ) according to:

$$
\hat{\mathrm{N}}_{\mathrm{b}(\mathrm{i}, \mathrm{j})}=\frac{\mathrm{b}}{2\left(\hat{\mathrm{~F}}-1 / \widetilde{\mathrm{S}}_{\mathrm{i}, \mathrm{j}}\right)}
$$

The standardized variance in allele frequency ( $\hat{\mathrm{F}}$ ) is calculated according to Pollack (1983). The parameter b is calculated analytically from age structure information and the number of years between samples (Tajima 1992). The age-at-maturity information required to calculate b was obtained from ecological data (Hillman et al. 2007). The harmonic mean of sample sizes from years $i$ and $j$ is $\tilde{S}_{\mathrm{i}, \mathrm{j}}$. The harmonic mean over all pairwise estimates of $\hat{\mathrm{N}}_{\mathrm{b}(\mathrm{i}, \mathrm{j})}$ is $\tilde{\mathrm{N}}_{\mathrm{b}}$. SALMONNb (Waples et al. 2007) was used to calculate $\tilde{\mathrm{N}}_{\mathrm{b}}$.

## Results and Discussion

In this section we combine our presentation and interpretations of the genetic analyses. Additionally, this section is organized based on the task list presented in the study plan.

Task 1 - Document the observed genetic diversity.

Substantial genetic diversity was observed over all Lake Wenatchee sockeye collections analyzed (Table 1), with heterozygosity estimates over all loci having a mean of 0.79 . Genetic diversity was consistent with expected Hardy-Weinberg random mating genotypic proportions for all collections. The $\mathrm{F}_{\text {IS }}$ observed for each collection was not statistically significant given the distribution of $\mathrm{F}_{\text {IS }}$ generated using a randomization procedure. Additionally, there were no statistically significant associations observed between alleles across loci (i.e., linkage equilibrium) (data not shown). We concluded from these results that the genetic data from each collection was consistent with statistical expectations for random association of alleles within and between loci. In other words, each collection represents samples from a single gene pool (i.e., populations), and the genetic diversity observed has no detectable technical artifacts or evidence of natural selection.

Task 2 - Test for differentiation among Lake Wenatchee collections and the associated supplementation program.

We explicitly tested the hypothesis of no significant differentiation within natural-origin or broodstock collections from Lake Wenatchee using a randomization chi-square test. The null hypothesis for these tests was that the allele frequencies from two different populations were drawn from the same underlying distribution. We show the results for the pairwise comparisons among eight temporally replicated natural-origin collections from Lake Wenatchee ( 28 pairwise tests), and report all tests were non-significant (Table 2A). Similarly, for five temporally replicated broodstock collections, 10 of 10 pairwise tests were non-significant (Table 2B). We also tested if natural-origin and broodstock
collections were differentiated from each other over time, and report that 40 of 40 tests were non-significant (Table 2C). The nominal level of statistical significance ( $\alpha=0.05$ ) was adjusted for multiple comparisons using strict Bonferroni correction (Rice 1989). Yet, there are perhaps slight differences between paired natural-broodstock collections. Note that the p-values for comparisons regarding 2006 and 2007 paired collections are lower than for comparisons regarding 2000, 2001, and 2004. The small sample sizes for broodstock collections in 2006 and 2007 may not have been random samples from the Lake Wenatchee sockeye population.

Given the consistencies observed for allele frequency distributions over time, metrics of population structure were expected to be small. This was the case, as the estimated $\mathrm{F}_{\text {ST }}$ over all thirteen collections was 0.0003 . This observed value fell within the distribution of $\mathrm{F}_{\mathrm{ST}}$ values expected if there were no population structure present (permutation test pvalue 0.12). Analysis of the paired natural-broodstock collections corroborated this result. Pairwise estimates of $\mathrm{F}_{\text {ST }}$ were 0.000 for years 2000, 2001, 2004, and 2007, and 0.002 for 2006. All five estimates were non-significant. Essentially, all 13 sockeye collections could be considered samples from the same population. Given these results, it is valid to combine all collections for statistical analysis. Therefore, we did not calculate genetic distances among any collections, as it is inappropriate to estimate distances that are effectively zero.

## Conclusions

We interpret these data to indicate that there appears to be no significant year-to-year differences in allele frequencies among natural-origin or broodstock collections, nor are there observed differences between collections pre- and post-supplementation. As a result, we accept the null hypothesis that the allele frequencies of the broodstock collections equal the allele frequencies of the natural collections, which equals the allele frequency of the donor population. Furthermore, the observed genetic variance that can be attributed to among collection differences was negligible.

Task 3 - Calculate $\mathrm{N}_{\mathrm{e}}$ using the temporal method for multiple samples from the same location to document trend.

The fundamental parameter for inferring $\mathrm{N}_{\mathrm{e}}$ using genetic data is the standardized variance in allele frequency ( $\hat{\mathrm{F}}$ ) (Pollack 1983). Methods estimate $\mathrm{N}_{\mathrm{e}}$ from observed changes in $\hat{F}$ over temporally replicated collections from the same location. Yet, as previously shown, there were no statistically significant differences detected in allele frequencies. The underlying model for estimating $\mathrm{N}_{\mathrm{e}}$ produced estimates with extremely large variances, given small temporal differences in $\hat{F}$, which rendered any trend in $\mathrm{N}_{\mathrm{e}}$ unobservable. Table 3 shows $\mathrm{N}_{\mathrm{e}}$ estimates calculated using temporally replicated natural collections.

Task 4-Compare $\mathrm{N}_{\mathrm{e}}$ estimates with trend in census size for Lake Wenatchee sockeye.

See Task 3

## Acknowledgements

We would like to thank Jeff Fryer (CRITFC) for providing critical collections of naturalorigin sockeye from Lake Wenatchee. We would like to thank Norm Switzler for collection curation and Ken Warheit and Denise Hawkins for helpful comments regarding this project. This project was funded by Chelan County PUD and the Washington State General Fund.

## Executive Summary

The main objective of this study was to determine the potential impacts of the Chiwawa River Supplementation Program on natural spring Chinook in the upper Wenatchee system. We did this by investigating population differentiation between temporally replicated Chiwawa River natural and hatchery samples from the Wenatchee River watershed using microsatellite DNA allele frequencies and the statistical assignment of individual fish to specific populations. Additionally, to assess the genetic effect of the hatchery program, we investigated the relationship between census and effective population sizes using collections obtained before and after the supplementation program. In this summary, we briefly describe the salient results contained within this report; however, each "Task" within the Results/Discussion section below contains extended coverage for each topic along with an expanded interpretation of each result.

Overall, we observed substantial genetic diversity within collections, with heterozygosities equal to roughly $80 \%$, over thirteen microsatellite markers. Microsatellite allele frequencies among temporally replicated collections from the same population (i.e., location) were variable, resulting in significant genetic differentiation among these collections. However, these difference are likely the result of salmon life history in this area, as four-year-old Chinook comprise a majority of returns each year. That is, the genetic tests are detecting the differences of contributing parents from each cohort, rather than a hatchery effect.

## Analysis of Chiwawa River Collections

To assess the multiple competing hypotheses regarding population differentiation within and among Chiwawa River collections, we found it necessary to organized the Chiwawa genetic data into three data sets: (1) fish origin (hatchery versus natural), (2) spawning location (hatchery broodstock versus in-river (natural) spawners), and (3) four "treatment" groups (1. hatchery-origin hatchery broodstock, 2. hatchery-origin natural spawner, 3. natural-origin natural spawner, and 4. natural-origin hatchery broodstock). We conducted separate analyses using each of the three data sets, with each analysis
touching on some aspect of the components necessary to move through the Conceptual Process outlined by Murdoch and Peven (2005).

Origin Dataset - We report that allele frequencies within and between natural- and hatchery-origin collections are significantly different, but there does not appear to be a robust signal indicating that the recent natural-origin collections have diverged greatly from the pre- or early post-supplementation collections. Genetic drift will occur in all populations, but does not appear to be a major factor affecting allele frequencies within the Chiwawa collections.

Spawning Location Dataset - There are significant allele frequency differences within and between hatchery broodstock and natural spawner collections. However, in recent years the allele frequency differences between the hatchery broodstock and natural spawner collections have declined. Furthermore, based on linkage disequilibrium, there is a genetic signal that is consistent with increasing homogenization of allele frequencies within hatchery broodstock collections, but a similar homogenization within the natural spawner collection is not apparent. These data suggest that there exists consistent year-to-year variation in allele frequencies among hatchery and natural spawning collections, but there is a trend toward homogenization of the allele frequencies of the natural- and hatchery-origin fish that compose the hatchery broodstock.

Four Treatment dataset - Although there are signals of allelic differentiation among Chiwawa River collections, there are no robust signs that these collections are substantially different from each other. We used two different analyses to measure the degree of genetic variation that exists among individuals and collections within the Chiwawa River. First, we conducted a principal component analysis using all Chiwawa samples with complete genotypes (i.e., no missing alleles from any locus). Although the first two principal component axes account for only $10.5 \%$ of the total molecular variance, a substantially greater portion of that variance is among individual fish, regardless of their identity, rather than among hatchery and natural collections. The
variances in principal component scores among individuals are 11 and 13 times greater than the variance in scores among collections.

Secondly, using an Analysis of Molecular Variance (AMOVA), we were able to determine how best to group populations, with "best" being defined as that grouping that accounts for the greatest proportion of among group (i.e., population) variance. Furthermore, by partitioning molecular variance into different hierarchical components, we are able to determine what level accounts for the majority of the molecular variance. The AMOVA results clearly show that nearly all molecular variation, no matter how the data are organized, resides within a collection. The percentage of total molecular variance occurring within collections ranged from $99.68 \%$ to $99.74 \%$. These results indicate that the significant differences among collections of Chiwawa fish account for less than one percent of the total molecular variance, and these differences cannot be attributed to fish origin or spawning location.

## Effective Population Size $\left(N_{e}\right)$

The contemporary estimate of $\mathrm{N}_{\mathrm{e}}$ calculated using genetic data combined for Chiwawa natural-origin spawners (NOS) and hatchery-origin spawners (HOS) Chinook is $\mathrm{N}_{\mathrm{e}}=386.8$, which is slightly larger than the pre-hatchery $\mathrm{N}_{\mathrm{e}}$ we estimated using demographic data from 1989 - 1992. Additionally, the $\mathrm{N}_{\mathrm{e}} / \mathrm{N}$ ratio calculated using 386.8 for $\mathrm{N}_{\mathrm{e}}$ and the arithmetic mean yearly census of NOS and HOS Chinook from 1989 2005 for N is 0.40 . These results suggest the $\mathrm{N}_{\mathrm{e}}$ has not declined during the period of Chiwawa Hatchery Supplementation Program operation.

## Analysis Of Upper Wenatchee Tributary Collections

We compared genetic data for spring Chinook collected from the major spawning aggregates of the Wenatchee River. We observed significant differences in allele frequencies among temporally replicated collections within populations, and among populations within the upper Wenatchee. However, these differences account for a very small portion of the overall molecular variance, and these populations overall are very similar to each other. Of all the populations within the Wenatchee River, the White River
appears to be the most distinct. Yet, this distinction is more a matter of detail than of large significance, as the median $\mathrm{F}_{\text {ST }}$ between White River collections and all other collections (except the Little Wenatchee collection; see Results/Discussion) is less than $1.5 \%$ among population variance. We consider the implications of these results in the Conclusion section that follows the Results/Discussion section. Additionally, there is no evidence that the Chiwawa River Supplementation Program has changed the allele frequencies in the Nason Creek and White River populations, despite the presence of hatchery-origin fish in both these systems.

## Introduction

Murdoch and Peven (2005) outlined 10 objectives to assess the impact (positive or negative) of hatchery operations mitigating the operation of Rock Island Dam. Two objectives relate to monitoring the genetic integrity of populations:

Objective 3: Determine if genetic diversity, population structure, and effective population size have changed in natural spawning populations as a result of the hatchery program. Additionally, determine if hatchery programs have caused changes in phenotypic characteristics of natural populations.

Objective 5: Determine if the stray rate of hatchery fish is below the acceptable levels to maintain genetic variation between stocks.

This study addresses Objective 3 (above), and documents analyses and results WDFW completed for populations of spring Chinook (Oncorhynchus tshawytscha) in the Wenatchee River watershed. This study was not intended to specifically address Objective 5 (above); however, genetic data provide results relevant to Objective 5. The critical component of Objective 3 is to determine if hatchery supplementation has effected change. Furthermore, change in this context means altering census size and/or genetic marker allele frequencies; we did not attempt to measure changes in fitness. Perhaps a more meaningful rewording of Objective 3 is, "Did the hatchery supplementation program succeed at increasing the census size of a target population while leaving genetic integrity intact?" In order to evaluate cause and effect of hatchery supplementation, we surveyed and compared genetic variation in samples collected before and after potential effects from the Chiwawa Hatchery Supplementation Program. Samples were acquired from the primary spawning aggregates in the upper Wenatchee River watershed: Nason Creek, Little Wenatchee River, White River, and Chiwawa River. Hatchery samples were acquired from programs that could potentially affect genetic composition of Wenatchee stocks, the integrated Chiwawa River stock (local stock), Leavenworth National Fish Hatchery spring Chinook (Carson Stock - non local), and Entiat NFH (Carson Stock - non local). Additionally, the genetic markers used were the Genetic Analysis of Pacific Salmonids (GAPS) (Seeb et al. in review) standardized
microsatellites, so all data from the Wenatchee study will be available for inclusion in the GAPS Chinook coastwide microsatellite baseline.

## History of Artificial Propagation

Artificial propagation in the upper Columbia River began in 1899 when hatcheries were constructed on the Wenatchee and Methow rivers (Mullan 1987). These initial operations were small, with the Tumwater Hatchery on the Wenatchee River releasing several hundred thousand fry, and the Methow River hatchery producing few Chinook salmon before it was closed in 1913 (Craig and Suomela 1941, Nelson and Bodle 1990). The Leavenworth State Hatchery operated in the Wenatchee River Basin between 1913 and 1931 using eggs from non-native stocks (Willamette River spring-run and lower Columbia Chinook hatchery fall-run). These early attempts at hatchery production were largely unsuccessful for spring-run Chinook (WDF 1934). Between 1931 and 1939, no Chinook salmon hatcheries were in operation above Rock Island Dam (Rkm 730).

In 1938, the last salmon was allowed to pass upstream through the uncompleted Grand Coulee Dam (Rkm 959). To mitigate the loss of habitat, adult Chinook salmon were trapped, under the auspices of the Grand Coulee Fish Maintenance Project (GCFMP), at Rock Island Dam beginning in May 1939, and relocated into three of the remaining accessible tributaries to the upper Columbia River: the Wenatchee, Entiat, and Methow Rivers. GCFMP transfers continued through the autumn of 1943. Spring- and summer/fall-run fish were differentiated at Rock Island Dam based on a 9 July cutoff date for Chinook arrivals at Rock Island Dam (Fish and Hanavan 1948). Spring-run adults collected at Rock Island Dam (pre 9 July fish) were either transported to Nason Creek on the Wenatchee River to spawn naturally (1939-43), or to the newly constructed Leavenworth NFH (1940) for holding and subsequent spawning (1940-43). Eggs were incubated on site or transferred to the Entiat NFH (1941) and Winthrop NFH (1941). In 1944 spring-run adults were allowed to freely pass Rock Island Dam. The GCFMP did not differentiate among late-run stocks (post 9 July fish) passing Rock Island Dam. Laterun offspring reared at the Leavenworth NFH, Entiat NFH, and Winthrop NFHs were an
amalgamation of summer and fall upper Columbia River populations (Fish and Hanavan 1948). Late-run fish were transplanted into the upper and lower Wenatchee, Methow, and Entiat Rivers.

After 1943, the Winthrop NFH continued to use local spring-run Chinook for hatchery production, while the other NFHs largely focused on summer-run Chinook salmon. Renewed emphasis on spring run production in the mid-1970s saw the inclusion of local and non-local eggs (Carson NFH stock, Klickitat River stock, and Cowlitz River stock) to the NFHs. In the early 1980s, imports of non-native eggs were reduced significantly, and thereafter the Leavenworth, Entiat, and Winthrop NFHs have relied on adults returning to their facilities for their egg needs (Chapman et al. 1995). Regarding late-run Chinook, due to the variety of methods employed to collect broodstock at dams, hatcheries, or the result of juvenile introductions into various areas, Chinook populations and runs (i.e., summer and fall) have been mixed considerably in the upper Columbia system over the past five decades (reviewed in Chapman et al. 1994).

Washington Department of Fish and Wildlife (WDFW) operates two facilities producing spring-run Chinook, the Methow Fish Hatchery (MFH) owned by Douglas County PUD that began operation in 1992 and Eastbank Fish Hatchery (EFH) owned by Chelan County PUD that began operation in 1989. Both programs were designed to implement supplementation (supportive breeding) programs for naturally spawning populations on the Methow and Wenatchee Rivers, respectively (Chapman et al. 1995). As part of the Rock Island Mitigation Agreement between Chelan County Public Utility District and the fishery management parties (RISPA 1989), a supplementation (supportive breeding) program was initiated in 1989 on the Chiwawa River to mitigate smolt mortality resulting from the operation of Rock Island Hydroelectric Project. EFH uses broodstock collected at a weir on the Chiwawa River, although in recent years hatchery fish have been collected at Tumwater Dam. Similarly, the MFHC uses returning adults collected at weirs on the Methow River and its tributaries, the Twisp and Chewuch Rivers (Chapman et al. 1995; Bugert 1998). Although low run size and trap efficiency has resulted in most broodstock being collected from the hatchery outfall or in some years Wells Dam,
progeny produced from these programs are reared at and released from satellite sites on the tributaries where the adults were collected. Numerous other facilities have reared spring-run Chinook salmon on an intermittent basis.

## Previous Genetic Studies - Population differentiation

Waples et al. (1991a) examined 21 polymorphic allozyme loci in samples from 44 populations of Chinook salmon in the Columbia River Basin. These authors reported three major clusters of Columbia River Basin Chinook salmon: 1) Snake River springand summer-run Chinook salmon, and mid and upper Columbia River spring-run Chinook salmon, 2) Willamette River spring-run Chinook salmon, 3) mid and upper Columbia River fall- and summer-run Chinook salmon, Snake River fall-run Chinook salmon, and lower Columbia River fall- and spring-run Chinook salmon. Utter et al. (1995) examined allele frequency variability at 36 allozyme loci in samples of 16 upper Columbia River Chinook populations. Utter et al. (1995) indicated that spring-run populations were distinct from summer- and fall-run populations, where the average genetic distance between spring-run and late-run Chinook were about eight times the average of genetic distances between samples within each group. Additionally, allele frequency differences among spring-run populations were considerably greater than that among summer- and fall-run populations in the upper Columbia River. Utter et al. (1995) also reported hatchery populations of spring-run Chinook salmon were genetically distinct from natural spring-run populations, but hatchery populations of fall-run Chinook salmon were not genetically distinct from natural fall-run populations.

As part of an evaluation of the relative reproductive success for the Chiwawa River supplementation program, Murdoch et al. (2006), used eleven microsatellite loci to assess population differentiation among spring Chinook salmon population samples in the upper Wenatchee River. Murdoch et al. (2006) reported a $>99 \%$ accuracy of correctly identifying spring-run and fall-run Chinook from the Wenatchee River. They also reported slight, but significantly different genetic variation among wild spring populations and between wild and hatchery stocks. Yet, since the spring-run populations
are genetically similar, identifying individuals genetically from the upper tributaries of the Wenatchee River was difficult. This result is exemplified in their individual assignment results, where $<8 \%$ of spring-run individuals, hatchery or wild, were correctly assigned using their criterion of an LOD (log of odds) score greater than 2. Murdoch et al. (2006) also reported contemporary natural spring Chinook show heterozygote deficit and low linkage disequilibrium (LD), while contemporary hatchery spring Chinook show heterozygote excess and high LD.

Williamson et al. (submitted) have continued the work of Murdoch et al. (2006) by analyzing Chiwawa River demographic data from 1989 - 2005 to estimate the proportions of recruits that were produced by Chinook with hatchery or wild origin. In an "ideal" population, the genetic size (i.e., effective size or $\mathrm{N}_{\mathrm{e}}$ ) and the census size are equal; however various demographic factors such as unequal sex ratios and variance in reproductive success among individuals reduces the genetic size below the census size. It is generally thought that the genetic size is approximately $10-33 \%$ the census size (Bartley et al. 1992; RS Waples pers. comm.), although values have been reported outside this range (Araki et al. 2007; Arden and Kapuscinski 2003; Heath et al. 2002). Despite being difficult to estimate, the effective population size in many respects is a more important parameter to know than census size, because $\mathrm{N}_{\mathrm{e}}$ determines how genetic diversity is distributed within populations and how the forces of evolution (i.e., forces that change genetic diversity over time) will affect the genetic variation present.

Williamson et al. (submitted) used demographic data to 1 ) investigate the effect of unequal sex ratio on genetic diversity, 2) investigate the effect of variation in reproductive success on genetic diversity, 3) investigate the effect of fluctuations in population size on genetic diversity, and 4) estimate the effective population size, using the inbreeding method (Ryman and Laikre 1991). Most importantly, they use demographic data from 1989 - 2000 to assess the impact of the Chiwawa Hatchery Supplementation Program on the effective population size of natural-origin Chiwawa River spring Chinook. They estimate that the $\mathrm{N}_{\mathrm{e}}$ of naturally spawning Chiwawa Chinook (i.e., both hatchery- and wild-origin fish on the spawning grounds) from 1989 -

1992 was $\mathrm{N}_{\mathrm{e}}=2683$ and in $1997-2000$ was $\mathrm{N}_{\mathrm{e}}=989$. They compare spawning ground $\mathrm{N}_{\mathrm{e}}$ to estimates calculated from combined broodstock and naturally spawning Chinook demographic data. The combined inbreeding $\mathrm{N}_{\mathrm{e}}$ estimate from $1989-1992$ was $\mathrm{N}_{\mathrm{e}}=$ 147 and in $1997-2000$ was $\mathrm{N}_{\mathrm{e}}=490$. Williamson et al. (submitted) argue that since the combined $\mathrm{N}_{\mathrm{e}}$ estimate is lower than the naturally spawning estimate, the supplementation program has had a negative impact on the Chiwawa River $\mathrm{N}_{\mathrm{e}}$.

Williamson et al. (submitted) also present genetic data for Chinook recovered on spawning grounds in upper Wenatchee River tributaries in 2004 and 2005. These genetic data are derived from the Murdoch et al. (2006) study. They compare samples collected from Chiwawa River (i.e., hatchery and wild), White River, Nason Creek, and Leavenworth Hatchery. Additionally, they include a 1994 Chiwawa River wild smolt sample for comparison with the 2004 brood year. Williamson et al. (submitted) report statistically significant genetic differentiation among Chiwawa River, White River and Nason Creek. Additionally, they report that the 1994 and 2004 Chiwawa River wild samples are not statistically different, but the 2004 Chiwawa wild and hatchery collections are statistically different.

## Study Objectives

This study investigated within and among population genetic diversity to assess the effect of the Chiwawa Hatchery's supplemental program on the natural Chiwawa River spring Chinook population. Differences among temporal population samples, the census size, heterozygosity, and allelic diversity were documented. We investigated population differentiation between the Chiwawa River natural and hatchery samples, and among all temporally replicated samples from the Wenatchee River watershed using microsatellite DNA allele frequencies and the statistical assignment of individual fish to specific populations. To assess the genetic effect of the hatchery program, correlation between census and effective population sizes were investigated using temporally replicated samples obtained before and after the supplementation program operation. To address the hypotheses associated with Objective 3 in Murdock and Peven (2005) we developed
eleven specific "Tasks" (Blankenship and Murdoch 2006), to which we analyzed specific genetic data. We present the results from these analyses specific to each individual Task.

## Methods and Materials

## Tissue collection and DNA extraction

We analyzed thirty-two population collections of adult spring Chinook salmon (Oncorhynchus tshawytscha) obtained from the Wenatchee River between 1989 and 2006 (Table 1). Nine collections of natural Chinook adults from the Chiwawa River ( $\mathrm{n}=501$ ), and nine collections of Chiwawa Hatchery Chinook ( $\mathrm{n}=595$ ) were collected at a weir located in the lower Chiwawa River. The 1993 and 1994 Chiwawa Hatchery samples are smolt samples from the 1991 and 1992 hatchery brood years, respectively. Additional samples were collected from upper Wenatchee River tributaries, White River, Little Wenatchee River, and Nason Creek. Six collections of natural White River Chinook ( $\mathrm{n}=179$ ), one collection from the Little Wenatchee ( $\mathrm{n}=19$ ), and six collections from Nason Creek ( $\mathrm{n}=268$ ) were obtained. Single collections were obtained for Chinook spawning in the mainstem Wenatchee River and Leavenworth National Fish Hatchery. An additional out-of-basin collection from Entiat River was also included in the analysis. Samples collected in 1992 or earlier are scale samples. All other samples were either fin clips or operculum punches, stored immediately in ethanol after collection. DNA was extracted from stored tissue using Nucleospin 96 Tissue following the manufacturer's standard protocol (Macherey-Nagel, Easton, PA, U.S.A.).

## Laboratory analysis

We performed polymerase chain reaction (PCR) amplification on each fish sample using the 13 fluorescently end-labeled microsatellite marker loci standardized as part of the GAPS project (Seeb et al. in review). GAPS genetic loci are: $O g o 2$, $O g o 4$ (Olsen et al. 1998); Oki100 (unpublished); Omm 1080 (Rexroad et al. 2001); Ots201b (unpublished); Ots208b, Ots211, Ots212, and Ots213 (Grieg et al. 2003); Ots 3 M , Ots 9 (Banks et al.
1999); OtsG474 (Williamson et al. 2002); Ssa408 (Cairney et al. 2000). PCR reaction volumes were $10 \mu \mathrm{~L}$, and contained $1 \mu \mathrm{~L} 10 \mathrm{x}$ PCR buffer (Promega), $1.0 \mu \mathrm{~L} \mathrm{MgCl2} \mathrm{(1.5}$ mM final) (Promega), $0.2 \mu \mathrm{~L} 10 \mathrm{mM}$ dNTP mix (Promega), and 0.1 units/mL Taq DNA polymerase (Promega). Loci were amplified as part of multiplexed sets, so primer molarities and annealing temperatures varied. Multiplex one had an annealing temperature of $50^{\circ} \mathrm{C}$, and used 0.37 Molar (M) Oki100, 0.35 M Ots 201 b , and 0.20 M Ots208b, and 0.20 M Ssa 408 . Multiplex two had an annealing temperature of $63^{\circ} \mathrm{C}$, and used $0.10 \mathrm{M} \mathrm{Ogo2}$, and 0.25 M of a non-GAPS locus (Ssa 197). Multiplex three had an annealing temperature of $56^{\circ} \mathrm{C}$, and used $0.18 \mathrm{M} \mathrm{Ogo4}, 0.18 \mathrm{M}$ Ots 213 , and 0.16 M OtsG474. Multiplex four had an annealing temperature of $53^{\circ} \mathrm{C}$, and used 0.26 M Omm1080, and 0.12 M Ots 3 M . Multiplex five had an annealing temperature of $60^{\circ} \mathrm{C}$, and used 0.30 M Ots $212,0.20 \mathrm{M}$ Ots 211 , and 0.10 M Ots 9 . Thermal cycling was conducted on either a PTC200 thermal cycler (MJ Research) or GeneAmp 9700 (Applied Biosystems) as follows: $95^{\circ} \mathrm{C}(2 \mathrm{~min}) ; 30$ cycles of $95^{\circ} \mathrm{C}$ for 30 sec ., 30 sec . annealing, and $72^{\circ} \mathrm{C}$ for 30 sec .; a final $72^{\circ} \mathrm{C}$ extension and then a $10^{\circ} \mathrm{C}$ hold. PCR products were visualized by electrophoresis on an ABI 3730 automated capillary analyzer (Applied Biosystems). Fragment analysis was completed using GeneMapper 3.7 (Applied Biosystems). Standardization of genetic data to GAPS allele standards was conducted following Seeb et al. (in review).

## Genetic data analysis

Assessing within population genetic diversity - Heterozygosity measurements are reported using Nei's (1987) unbiased gene diversity formula (i.e., expected heterozygosity) and Hedrick's (1983) formula for observed heterozygosity. Both tests are implemented using the microsatellite toolkit (Park 2001). We used GENEPOP version 3.4 (Raymond and Rousset 1995) to assess Hardy-Weinberg equilibrium (HWE), where deviations from the neutral expectation of random associations among alleles are calculated using a Markov chain method (5000 iterations in this study) to obtain unbiased estimates of Fisher's exact test. Global estimates of $\mathrm{F}_{\text {IS }}$ according to Weir and Cockerham (1984) were calculated using GENEPOP version 3.4. Genotypic linkage disequilibrium was calculated following Weir (1979) using GENEPOP version 3.4.

Linkage results for population collections are reported as the proportion of pairwise (locus by locus) tests that are significant (alpha $=0.01$ ). Linkage disequilibrium is considered statistically significant if more than $5 \%$ of the pairwise tests based on permutation are significant for a collection.

Within- and among-population genetic differentiation - The temporal stability of allele frequencies within populations, and pairwise differences in allele frequencies among populations were assessed using several different procedures. First, we tested for differences in allele frequencies among populations defined in Table 1 using a randomization chi-square test implemented in GENEPOP version 3.4 (Raymond and Rousset 1995). This procedure tests for differences between pairs of populations where alleles are randomized between the populations (i.e., genic test). The null hypothesis for this test is that the allele frequency distributions between two populations are the same. A low p-value should be interpreted as the allele frequency distributions being compared are unlikely to be samples drawn from the same underlying distribution.

Second, to graphically describe allele frequency differences among populations we conducted a nonmetric multidimensional scaling analysis using allele-sharing distance matrices from two different data sets. Pairwise allele-sharing distances are calculated as 1 - (mean over all loci of the sums of the minima of the relative frequencies of each allele common to a pair of populations). To calculate the allele-sharing distances for each pair of populations we used PowerMarker v3.25 (Liu and Muse 2005). Nonmetric multidimensional scaling is a technique designed to construct an $n$-dimensional "map" of populations, given a set of pairwise distances between populations (Manly 1986). The output from this analysis is a set of coordinates along n-axes, with the coordinates specific to the number of $n$-dimensions selected. To simplify our analysis we selected a 2-dimensional analysis to represent the relative positions of each population in a typical bivariate plot. The goodness of fit between the original allele-sharing distances and the pairwise distances between all populations along the 2-dimensional plot is measured by a "stress" statistic. Kruskal (in Rohlf 2002) developed a five-tier guide for evaluating stress levels, ranging from a perfect fit (stress=0) to a poor fit (stress=0.40). We
conducted the nonmetric multidimensional scaling analysis for one data set containing Chiwawa natural- and hatchery-origin collections, and another data set containing Chiwawa broodstock and in-river spawner collections. We used the mdscale module in MATLAB R2006b (The Mathworks 2006) to generate the nonmetric multidimensional scaling coordinates.

We examined the geographic and temporal structure of populations in the upper Wenatchee (Chiwawa River, Nason Creek, and White River, only) using a series of analyses of molecular variance (AMOVAs). Here, we defined an AMOVA as an analysis of variance of allele frequencies, as originally designed by Cockerham (1969), but implemented in Arlequin v2.1 (Schneider et al. 2000). These analyses permit populations to be aggregated into groups, and molecular variance is then partitioned into within collections, among collections, but within groups, and among group components. With this approach, we were able to determine how best to group populations, with "best" being defined as that grouping that accounts for the greatest proportion of among group variance. Furthermore, by partitioning molecular variance into three different hierarchical components, we are able to determine what level accounts for the majority of the molecular variance.

Finally, we explored the partitioning of molecular variance between among-individuals and among-populations using a principal component analysis and multi-locus estimates of pairwise $\mathrm{F}_{\text {ST }}$, estimated by a "weighted" analysis of variance (Weir and Cockerham, 1984). Principal component analysis is a data-reduction technique whereby the correlation structure among variables can be used to combine variables into a series of multivariate components, with each original variable receiving a weighted value for each component based on its correlation with that component. Here, we used a program written by Warheit in MATLAB R2006b (The Mathworks 2006) that treats each allele for each locus as a single variable ( 13 loci $=26$ alleles or variables), and these 26 "variables" were arranged into 26 components, with each component accounting for a decreasing amount of molecular variance. Estimates of $\mathrm{F}_{\text {ST }}$ were calculated using GENETIX version 4.05 (Belkhir et al.1996). To determine if the $\mathrm{F}_{\text {ST }}$ estimates were
statistically different from random (i.e., no structure), 1000 permutations were implemented in GENETIX version 4.05 (Belkhir et al.1996).

Effective population size ( $\mathbf{N}_{\mathbf{e}}$ ) - Estimates of the effective population size were obtained using two methods, a multi-collection temporal method (Waples 1990), and a singlecollection method (Waples 2006) using linkage disequilibrium data. The temporal method assumes that cohorts are used, but we did not decompose the collection year samples into their respective cohorts using age data. Therefore, $\mathrm{N}_{\mathrm{e}}$ estimates that pertain to individual year classes of breeders are not valid; however the harmonic mean over all samples will estimate the contemporary $\mathrm{N}_{\mathrm{e}}$. Comparing samples from years $i$ and $j$, Waples' (1990) temporal method estimates the effective number of breeders $\left(\hat{\mathrm{N}}_{\mathrm{b}(\mathrm{i}, \mathrm{j})}\right)$ according to:

$$
\hat{\mathrm{N}}_{\mathrm{b}(\mathrm{i}, \mathrm{j})}=\frac{\mathrm{b}}{2\left(\hat{\mathrm{~F}}-1 / \hat{\mathrm{S}}_{\mathrm{i}, \mathrm{j}}\right)}
$$

The standardized variance in allele frequency ( $\hat{\mathrm{F}}$ ) is calculated according to Pollack (1983). The parameter b is calculated analytically from age structure information and the number of years between samples (Tajima 1992). The age-at-maturity information required to calculate b was obtained from Murdoch et al. (2006) for this analysis. They observed for Chiwawa Hatchery Chinook that $8.6 \%$ matured at age 2, $4 \%$ at age 3, 87\% at age 4 , and $0.4 \%$ at age 5. For Chiwawa natural Chinook, Murdoch et al. (2006) observed that $1.8 \%$ matured at age $3,81.6 \%$ at age 4 , and $16.7 \%$ at age 5 . The harmonic mean of sample sizes from years $i$ and $j$ is $\widetilde{\mathrm{S}}_{\mathrm{i}, \mathrm{j}}$. Over all pairwise comparisons the harmonic mean of all $\hat{\mathrm{N}}_{\mathrm{b}(\mathrm{i}, \mathrm{j})}$ is $\widetilde{\mathrm{N}}_{\mathrm{b}}$, the contemporary estimate of the effective population size $\left(\mathrm{N}_{\mathrm{e}}\right)$. SALMONNb (Waples et al. 2007) was used to calculate $\tilde{\mathrm{N}}_{\mathrm{b}}$. As suggested by authors, alleles with a frequency below 0.05 were excluded from the analysis to reduce potential bias.

The method of Waples (2006) uses linkage disequilibrium (i.e., mean squared correlation of allele frequencies at different gene loci) as a means of estimating effective population size $\left(N_{e}\right)$ from a single sample. While this method is biased in some cases where $N_{e} / N$
ratio is less the 0.1 and the sample size is less than the true $\mathrm{N}_{\mathrm{e}}$, it has been shown to produce comparable results to the temporal method. Burrows' delta method is used to estimate LD, and a bias corrected estimate of $\mathrm{N}_{\mathrm{e}}$ is calculated after eliminating alleles with frequency less than 0.05 . This test was implemented using $\operatorname{LDN}_{\mathrm{e}}$ (Do and Waples unpublished). In age-structured species, $\mathrm{N}_{\mathrm{e}}$ estimates based on LD are best interpreted as the effective number of breeders $\left(\mathrm{N}_{\mathrm{b}}\right)$ that produced the sample (Waples 2006). $\mathrm{N}_{\mathrm{b}}$ should be multiplied by the mean generation length (i.e., 4 in this case) to obtain an overall estimate of $\mathrm{N}_{\mathrm{e}}$ based on an $\mathrm{N}_{\mathrm{b}}$ estimate. We analyzed collections categorized by spawning location (i.e., hatchery broodstock or in-river) and did not analyze collections categorized by origin (i.e., hatchery or natural). Waples' (2006) method estimates $\mathrm{N}_{\mathrm{e}}$ from observed LD, therefore the corresponding $\mathrm{N}_{\mathrm{e}}$ estimates for the hatchery collections would be low and the estimates for the natural collections would be high. Yet, since the supplementation program is integrated, and hatchery fish can spawn naturally, we feel it inappropriate to analyze the hatchery and natural samples as if they were separate, which would essentially partition all the LD into the hatchery samples.

Each collection has an $\mathrm{N}_{\mathrm{b}}$ estimate and an associated confidence interval. If the confidence interval includes infinity, it means that sampling error accounts for all the LD observed (i.e., empirical LD is less than expected LD). The usual interpretation is that there is no evidence for any disequilibrium caused by genetic drift in a finite number of parents. Since the LD method estimates the number of breeders that contributed to the sample being analyzed, in order to calculate an $\mathrm{N}_{\mathrm{e}} / \mathrm{N}$ ratio, the appropriate census size must be used. The census size used to derive a ratio was the estimate four years prior to the collection analyzed using LD, which assumed a strict four-year-old lifecycle, although the observed proportion of four-year-olds was approximately $85 \%$ each year. The census numbers (Table 2) used to calculate the ratios for Chiwawa broodstock and in-river spawners were combined NOS (natural-origin spawners) and HOS (hatcheryorigin spawners) census estimates.

Individual assignment - A population baseline file was constructed containing all 1704 individual Chinook from 34 population collections (Table 1; Chiwawa origin data set
plus all samples from other populations). All individuals in the baseline had geneotypes that included nine or more loci. Individual Chinook were assigned to their most likely population of origin based on the partial Bayesian criteria of Rannala and Mountain (1997), using a "jack-knife" procedure, where each individual to be assigned was removed from the baseline prior to the calculation of population likelihoods. This procedure was implemented in a program written by Warheit in MATLAB R2006b (The Mathworks 2006). Two assignment criteria were used, 1) the population with the largest posterior probability for an individual was the "most-likely" population of origin (i.e., all individuals assigned to a collection), and 2) an assignment was consider valid only if the posterior probability was greater than or equal to 0.9 . Please note that while the analysis used 34 population collections to assign Rannala and Mountain likelihoods for each individual, these likelihoods were aggregated based on "population" (i.e., Chiwawa, Nason, White, and so on) and posterior probabilities were calculated for population location, rather than individual collections.

## Results and Discussion

In this section we combine our presentation and interpretations of the genetic analyses. Additionally, this section will be organized based on the task list presented in the study plan. Overall conclusions are provided following this section.

## Task 1: Determine trend in census size for Chiwawa River spring Chinook.

Census data from 1989-2005 are provided in Table 2 for the Chiwawa Hatchery broodstock and spring Chinook present in the Chiwawa River. The demographic data for naturally spawning Chinook are based on redd sampling and carcass surveys, while broodstock data are based on Chiwawa hatchery records. As the supplementation program is integrated by design, we also present the proportion of natural-origin broodstock ( pNOB ) incorporated into the hatchery, in addition to the number of naturalorigin (NOS) and hatchery-origin (HOS) spawners present in Chiwawa River. The
census size fluctuated yearly, and a general reduction in census size was observed in the mid to late 1990's. This trend was apparent in both the broodstock and in the river. The arithmetic mean census size from 1989 - 2005 for the Chiwawa Hatchery (i.e., broodstock) was $\mathrm{N}=87.5$ per year. The arithmetic mean census size from 1989 - 2005 for the Chiwawa River (i.e., NOS and HOS combined) was $\mathrm{N}=961.9$ per year. For collection years when adult Chiwawa hatchery-origin fish would have been absent in the Chiwawa River (1989-1992), the arithmetic mean of natural Chiwawa Chinook census size is $\mathrm{N}=962.7$. We will use this number as the baseline census size to assess if census size has changed. We used two different values for the contemporary census size in the Chiwawa River, NOS only and NOS + HOS. Additionally, we used collection years 2002-2005 for the contemporary NOS and HOS estimates, as these are the most recent data and the number of years included for estimation is the same as the pre-hatchery estimate above (i.e., four years). For NOS only, the arithmetic mean census size from 2002-2005 was $\mathrm{N}=536.0$. For total census size (i.e., NOS and HOS combined), the arithmetic mean census size from 2002 - 2005 was $\mathrm{N}=1324.0$. For the demographic data presented here, the contemporary census size is larger than the census estimate derived from the years prior to hatchery operation.

## Task 2: Document the observed genetic diversity.

## Genetic Diversity Categorized By Origin

For Chiwawa River collections categorized by origin (Table 1A), substantial genetic diversity was observed, with heterozygosity estimates over all loci, having a mean of 0.80. Genetic diversity was consistent with expected Hardy-Weinberg random mating genotypic proportions for ten of the eighteen collections. Eight of the nine Chiwawa natural collections were consistent with HWE, and two of nine Chiwawa Hatchery collections were consistent with HWE. $\mathrm{F}_{\text {IS }}$ is observed to be slight for all Chiwawa population collections, suggesting individuals within collections do not show excessive homozygosity.

The deviations from HWE observed were generally associated with hatchery collections. The two smolt collections (i.e., 1993 and 1994) showed significant deviations from HWE, which may be a function of non-random hatchery practices involving the contributing natural-origin parental broodstocks (i.e., 1991 and 1992 cohort). Deviations from HWE in the remaining hatchery collections may be the result of few individuals being represented in the broodstock (see below).

Additionally, linkage disequilibrium (LD) was also common for Chiwawa hatcheryorigin collections and minimal for Chiwawa natural-origin collections. The random association of alleles between loci (i.e., linkage equilibrium) is expected under ideal conditions. LD is observed when particular genotypes are encountered more than expected by chance. Laboratory artifacts (e.g. null alleles) or physical linkage of loci on the same chromosome can cause LD, but the LD we observed was not associated with certain locus combinations, which you would expect if either artifacts or physical linkage were the cause of LD. LD was observed for seven of the nine hatchery-origin collections. As with the deviations from HWE, the high LD in the 1993 and 1994 hatchery-origin collections may be a result of non-random hatchery practices. The substantial LD observed in the hatchery-origin adult collections (collection years 2000, 2001, 2004, and 2006) might be the result of small parental broodstock sizes contributing to those returning adults. During the mid 1990's, the Chiwawa broodstock size was low, with zero individuals collected in 1995 and 1999; so fewer individuals would be contributing to the hatchery adult returns than the natural. This idea is corroborated by the lower LD observed for the 2005 hatchery-origin collection, which had a contributing parental broodstock size in 2001 (i.e., the major contributing parental generation) approximately eight times as large as the previous few collection years (Table 2). LD reappears in the 2006 Chiwawa hatchery-origin collection, which had a contributing parental broodstock size (i.e., for the most-part, the 2002 hatchery brood year) five times lower (Table 2) than that of the 2005 collection.

While seven of nine hatchery-origin collections showed significant LD, only one natural origin collection showed LD, and for this collection, only $10 \%$ of the loci-pairs were in
disequilibrium (Table 1). The fact that LD predominated in the hatchery samples, suggests that variance in reproductive success (i.e., overrepresentation of particular parents) is higher in the hatchery-origin than in natural-origin collections.

## Genetic Diversity Categorized By Spawning Location

For upper Wenatchee River collections categorized by spawning location (Table 1B), substantial genetic diversity was observed, with heterozygosity estimates over all loci, having a mean of 0.79 and ranging from a low of 0.69 (1993 White River) to 0.85 (1993 Little Wenatchee). Genetic diversity was consistent with HWE for nineteen of twentynine population collections. For the collections that departed from HWE, seven were from the Chiwawa River, one was from Leavenworth Hatchery, one was the Wenatchee mainstem collection of hatchery-origin - naturally spawning fish, and one was from the White River. $\mathrm{F}_{\text {IS }}$ is observed to be slight for all population collections except the 1993 White River collection ( $10 \%$ heterozygote deficit) (Table 1B). Collections deviating with HWE generally correlated with collections having high LD. Twelve population collections showed a proportion of pairwise linkage disequilibrium tests (across all loci) greater than 5\% (Table 1B), eight of which were Chiwawa collections.

Starting in 1996, spawning location collections are composed of both natural- and hatchery-origin samples. The LD seen in the later spawning location collections may be caused by an admixing effect (i.e., mixing two populations), where random mating has not had the chance to freely associate alleles into genotypes. Interestingly, there appears to be a trend of reducing LD through time within the broodstock collections (Table 1B), which suggests that a "homogenizing" effect is taking place within the Chiwawa River. This observation is discussed more fully in Task 3 below.

## Task 3: Test for population differentiation among collections within the Chiwawa River and associated supplementation program.

## Introduction

Task 3 was designed to address two hypotheses listed as part of Objective 3 in Murdoch and Peven (2005):

- Ho: Allele frequency Hatchery $=$ Allele frequency ${ }_{\text {Naturally produced }}=$ Allele frequency $_{\text {Donor pop }}$.

Murdoch and Peven (2005) proposed these two hypotheses to help evaluate the Chiwawa supplementation program through the "Conceptual Process" (Figure 5 in Murdoch and Peven 2005; repeated here as Figure 1). There are two components to the first hypothesis, which must be considered separately. The first component involves comparisons between natural-origin populations in the Chiwawa to determine if there have been changes in allele frequencies or genetic distances, through time starting with the donor population. Documenting a change does not necessarily indicate that the supplementation program has directly affected the natural origin fish, as additional tests would be necessary to support that hypothesis. The intent of the second component is to determine if the hatchery produced populations have the same genetic composition as the naturally produced populations.

Although on the surface these two components and their associated comparisons may appear simple, from a hypothesis-testing perspective the analyses are complicated by the fact that natural-origin fish may have had hatchery-origin parents, and hatchery-origin fish may have had natural-origin parents. As such, we organized the Chiwawa genetic data into three data sets: (1) fish origin (hatchery versus natural), (2) spawning location (hatchery broodstock versus in-river (natural) spawners), and (3) four "treatment" groups (1. hatchery-origin hatchery broodstock, 2 . hatchery-origin natural spawner, 3. naturalorigin natural spawner, and 4. natural-origin hatchery broodstock). We conducted separate analyses using each of the three data sets, with each analysis touching on some aspect of the components necessary to move through the Conceptual Process (Figure 1).

## Hatchery- Versus Natural-Origin

We address the following questions with the origin data set:

1. Are there changes in allele frequencies and allele sharing distances in the naturalorigin collections from pre-supplementation to today?
2. Are there changes in allele frequencies and allele sharing distances in the hatchery-origin collections from early supplementation to today?
3. Are there significant differences in allele frequencies and large allele sharing distances between hatchery- and natural-origin adults from a collection year, and has this pattern changed through time?

Genic Differentiation Tests - We explicitly tested the hypothesis of no significant differentiation within natural- or hatchery-origin collections from the Chiwawa River using a randomization chi-square test. We show the results for the pairwise comparisons among natural-origin collections from the Chiwawa River populations in the first block of the second page of Table 3. Ten of the 36 ( $28 \%$ ) pairwise comparisons have highly significant allele frequency differences, while only 12 of the 36 comparisons ( $33 \%$ ) showed no significant differences. Eight of these 12 comparisons involved the 1996 collection, which included only eight samples and therefore provided little power to differentiate allele frequencies. If we exclude the 1996 collection, only $14 \%$ of the pairwise comparisons showed no significant differences, and here all but one of these comparisons involved the 1989 collection. The 1989 collection appeared to be the least differentiated collection in the natural-origin data set in that all pairwise comparisons were either not significant, or only mildly significant at the nominal critical value. No comparisons involving the 1989 collection were significant using a Bonferroni-corrected critical value, and 1989 is the only natural-origin collection in our data set that can be classified as "pre-supplementation."

We can interpret these results to indicate that although there appears to be significant year-to-year differences in allele frequencies among post-supplementation collections, the allele frequencies between each post-supplementation collection and the 1989 presupplementation collection are not greatly different. However, the level of differentiation
does increase from the early post-supplementation years to the more recent years (2001, 2004-2006), although the statistical level of this significance never exceeds the Bonferroni-corrected critical value. Finally, sample sizes were also small for the 1989 collection ( $\mathrm{n}=36$ ) and we cannot eliminate a reduction in power as a contributing factor for the lack of significance for these tests.

As with the hatchery-origin collections, most pairwise comparisons of allele frequencies between hatchery-origin samples were significant (Table 3, first page, upper block). Out of the 36 pairwise comparisons, all but three are significant at some level, and most comparisons are highly significant. Similar to the natural-origin analysis, the nonsignificant results were limited to comparisons involving the 1996, which included only eight samples.

As a result of this analysis we reject the hypothesis that there was no significant differentiation among natural- or hatchery-origin collections from the Chiwawa River. Furthermore, the allele frequencies of the hatchery-origin collections are significantly different from those of natural-origin collections (Table 3, first page, second block). For those fish collected in the same year, allele frequencies are significantly different between hatchery- and natural-origin collections, although in 2005 the level of significance was below the Bonferroni critical value (Table 3). The next step is to examine the pattern of allelic differentiation to discover first if there is a trend among the data, and second, if this trend suggests that the allele frequency differences among Chiwawa River natural-origin fish collections has been affected by the hatchery-origin fish.

Allele-sharing and Nonmetric Multidimensional Scaling - We constructed a pairwise allele-sharing distance matrix for all hatchery- and natural-origin collections from the Chiwawa River and subjected this matrix to a nonmetric multidimensional scaling analysis, restricting the analysis to two dimensions (Figure 2). The stress statistic for this analysis is 0.09 , a value Kruskal (in Rohlf 2002) listed as a good to excellent fit between the actual allele-sharing distances and the Euclidean (straight-line) distances in the plot.

In other words, Figure 2 is a good visual representation of the allele sharing distance matrix; collections with a high percentage of alleles shared will be closer to each other than collections with a lower percentage of alleles shared.

With the exception of the two outlier years (1996 and 1998) the Chiwawa natural-origin collections form a tight cluster indicating an overall common set of shared alleles among these collections. Even if we ignore the 1996 and 1998 hatchery-origin collections, there appears to be a greater variance in shared alleles among the Chiwawa hatchery-origin collections than the natural-origin collections (Figure 2). In fact, the median percentage of alleles shared among the Chiwawa natural-origin collections is $76 \%$ compared with $69 \%$ alleles shared among the Chiwawa hatchery-origin collections.

Also, there appears to be a convergence in allele sharing distances (i.e., a decrease in allele frequency differences) between the hatchery- and natural-origin fish from the late 1980s/early 1990s to 2006. The series of red arrows in Figure 2 represent the progression of change in hatchery-origin allele sharing distances from 1996 (first adult hatchery origin fish in our analysis) to 2006 and this progression is decidedly in the direction of the natural-origin cluster. However, the most recent natural-origin collections (2001, 2004-2006) appear to have pulled closer to the hatchery-origin collections, compared with the 1989 natural-origin collection (note the close proximity of the 2000 and 1989 natural-origin collections). Nevertheless, the cluster of natural-origin collections adjacent to the hatchery-origin collections in Figure 2 also includes the 1993 natural-origin collection. Qualitatively, it appears that the initial hatchery-origin and natural-origin collections were more different from each other in terms of the percentage of shared alleles than are the most recent hatchery- and natural-origin collections. This may have been a result of a non-random sample of natural-origin fish that was used as broodstock in the initial years of the supplementation program (see discussion in Task 2 concerning deviations from HWE and linkage disequilibrium).

That being said, we do need to emphasize that Figure 2 is dominated by five outlier collections (two each from the 1996 and 1998 collections, and the 1994 smolt collection).

The 1996 and 1998 collections are characterized by small samples sizes, and the 1994 smolt collection has nearly all pairs of loci in linkage disequilibrium (Table 1). If we eliminate these five outlier groups, both the hatchery- and natural-origin collections form a relatively tight cluster. Excluding the five outliers, the median percentage of shared alleles among all pairwise combinations of Chiwawa hatchery versus Chiwawa natural collections is $76 \%$. This compares with a median pairwise percentage of $79 \%$ among only Chiwawa natural-origin collections. That is, there are nearly as many alleles shared between the hatchery-origin and natural-origin collections as there are among the naturalorigin collections themselves. There is also a narrowing of differences between naturaland hatchery-origin fish from the same collection years from 1993 ( $76 \%$ shared alleles) through 2006 (83\% shared alleles).

If allelic differentiation among collections is a function of genetic drift, we would expect a positive correlation between the number of years between two collections and the allele sharing distance. That is, if genetic drift is the primary cause of allele frequency differences between two collections, the greater the number of years between the two collections the larger the allele-sharing distance. For both the natural- and hatcheryorigin collections we examined the relationship between the number of years between a pair of collections and the collections' allele-sharing distance (Figure 3). Although the relationship between time interval and allele distance appears to be a positive function in the natural collections, the slope of the regression line is 0.0017 , and is not significantly different from zero. Furthermore, the correlation coefficient $\left(\mathrm{r}^{2}\right)$ equals 0.1068 , which means that the time interval between collections accounts for only $10 \%$ of the pairwise differences in allelic distance. The hatchery-origin collections do show a significantly positive slope ( $0.0037 ; \mathrm{p}=0.0254$ ) and a regression coefficient nearly three times greater than that for the natural-origin collections. However, the correlation coefficient is still relatively small ( $r^{2}=0.3290$ ), indicating that the time interval between collections accounts for one-third of the pairwise differences in allelic distance. The results suggest that if genetic drift is a factor in allelic differentiation between collections, it is only a minor factor, and appears to have affected the hatchery-origin collections more than the natural-origin collections.

If four-year-old fish dominate each collection year, we would expect a closer relationship among collections that are spaced at intervals of four years. The average percentage of alleles shared between two natural-origin collections that are separated by four years or a multiple of four years is $81 \%$, compared with $78 \%$ for natural-origin collections separated by years that are not divisible by four. Likewise, for hatchery-origin collections the average percentage of alleles shared is $80 \%$ and $75 \%$ for collections separated by years divisible and not divisible by four, respectively. Although the percent differences described above are relatively small, they are consistent with the idea that allelic differences between collections are a function of year-to-year variability among different cohorts of four year-old fish.

Summary - The allele frequencies within and between natural- and hatchery-origin collections are significantly different, but there does not appear to be a robust signal indicating that the recent natural-origin collections have diverged greatly from the pre- or early post-supplementation collections. Genetic drift will occur in all populations, but does not appear to be a major factor with the Chiwawa collections. We propose that the differences among collections are a function of differences in allele frequencies among cohorts of the four year-old fish that dominate each collection.

## Hatchery Broodstock Versus Natural (In-River) Spawners

We address the following questions with the spawner data set:

1. Are there changes in allele frequencies and allele sharing distances in the natural spawning collections from pre-supplementation to today?
2. Are there changes in allele frequencies and allele sharing distances in the hatchery broodstock collections from early supplementation to today?
3. Are there significant differences in allele frequencies and large allele sharing distances between hatchery and natural spawning adults from a collection year, and has this pattern changed through time?

Genic Differentiation Tests - For the most part there are significant differences in allele frequencies among collections for both the hatchery broodstock and natural spawners (Table 4), and these differences are consistent with the origin data set (Table 3). There are four collection years with paired samples (2001, 2004-2006) where we can compare allele frequency differences between the hatchery broodstock and natural spawners, within the same year. The 2001 hatchery broodstock and natural spawner collections have significantly different allele frequencies, but the level of significance decreased from 2001 to 2004, and become non-significant in 2005 and 2006 (Table 4). This indicates that by 2005, the hatchery broodstock and natural spawners collections were effectively sampling from the same population of fish. Additionally, the percentage of alleles shared between the hatchery broodstock and the natural spawners increased from $76 \%$ in 2001 to $86 \%$ in 2006 (allele sharing distance matrix, not shown). From this analysis, we conclude that although there are year-to-year differences in allele frequencies within the natural and hatchery spawner collections, there appears to be a convergence of allele frequencies within collection-year, between the natural and hatchery spawner populations.

Linkage Disequilibrium - Linkage disequilibrium is the correlation of alleles between two loci, and can occur for several reasons. If two loci are physically linked on the same chromosome, than alleles from each of these loci should be correlated. However, linkage between two loci can occur as a result of population bottlenecks, small population sizes, and natural selection. If any of these conditions had occurred or were occurring within the Chiwawa River system, we would expect to find substantial linkage disequilibrium in many or perhaps all Chiwawa collections. However, many Chiwawa collections, especially the natural-origin collections, do not show linkage disequilibrium (Table 1), and it would appear that the linkage disequilibrium within certain Chiwawa collections is not a function of the processes listed above. Linkage disequilibrium can also result if the collection is composed of an admixture. That is, if two or more reproductively isolated populations are combined into a single collection, the collection will show linkage disequilibrium. Each broodstock and natural spawning collection is composed of naturaland hatchery-origin fish. If these hatchery- and natural-origin fish are drawn from the
same population, the spawning collections should not show substantial linkage disequilibrium. However, if the hatchery- and natural-origin fish are from different populations (i.e., full hatchery - natural integration has not been achieved), the spawning collections should show substantial linkage disequilibrium.

There are only three Chiwawa spawning collections that are not composed of both hatchery- and natural-origin samples: 1989 (natural-origin, natural spawner), 1993 (natural-origin, hatchery broodstock), and 2001 (natural-origin, natural spawner). Of the 10 spawning collections with both hatchery- and natural-origin fish, seven show significant linkage disequilibrium. Two of the three collections that did not show linkage disequilibrium are the 1996 and 1998 hatchery broodstock collections, which are composed of only seven natural- and six hatchery-origin fish, and two natural- and 19 hatchery-origin fish, respectively. Within the hatchery broodstock collections with linkage disequilibrium, the percent of loci pairs showing linkage decreased from $32 \%$ in 2000 to $13 \%$ in 2001 and 2004, to only $1 \%$ and $5 \%$ in 2005 and 2006, respectively (Table 1). If the homogenization of allele frequencies of natural- and hatchery-origin fish was increasing from 2000 to 2006, we would expect a decrease in linkage disequilibrium among the broodstock collections. This is what occurred within the hatchery broodstock collections, but did not occur within the natural spawner collections, where the percent of loci pairs showing linkage was $18 \%$ in $2004,6 \%$ in 2005, and $10 \%$ in 2006 (Table 1). Furthermore, the 2001 natural spawner collection, with no hatchery-origin component showed linkage disequilibrium with $9 \%$ of loci pairs.

There is no correlation between percent of loci pairs showing linkage disequilibrium and percent of broodstock composed of hatchery-origin fish $\left(r^{2}=0.0045\right)$. Furthermore, the natural spawner and hatchery broodstock collections were each composed of roughly the same average percentage of hatchery-origin fish ( $57 \%$ and $53 \%$, respectively). If the decrease in linkage disequilibrium among the hatchery broodstock collections from 2000 to 2006 was a result of a homogenization of allele frequencies of natural- and hatcheryorigin fish in the broodstock, the same degree of homogenization did not occur within the
natural spawner collections. This would occur if natural- and hatchery-origin fish spawning within the river remain segregated, either by habitat or by fish behavior.

Summary - As with the origin data set, there are significant allele frequency differences within and between hatchery broodstock and natural spawner collections. However, in recent years the allele frequency differences between the hatchery broodstock and natural spawner collections has declined. Furthermore, based on linkage disequilibrium, there is a genetic signal that is consistent with increasing homogenization of allele frequencies within hatchery broodstock collections, but a similar homogenization within the natural spawner collection is not apparent. These data suggest that there exists consistent year-to-year variation in allele frequencies among hatchery and natural spawning collections, but there is a trend toward homogenization of the allele frequencies of the natural- and hatchery-origin fish that compose the hatchery broodstock.

## Four Treatment Groups

Analyses of genetic differences between hatchery (broodstock) and natural spawner collections is confounded by the fact that each these two groups are composed of fish of natural- and hatchery-origin. To understand the effects of hatchery supplementation on natural-origin fish that spawn naturally, we needed to divide the Chiwawa data set into four mutually exclusive groups: (1) hatchery-origin hatchery broodstock, (2) hatcheryorigin natural spawner, (3) natural-origin hatchery broodstock, and (4) natural-origin natural spawner, with each group consisting of multiple collection years, for a total of 25 different groups.

Allele-sharing and Nonmetric Multidimensional Scaling -As with previous analyses discussed above, we constructed a pairwise allele-sharing distance matrix for all collections from each of these treatment groups and subjected this matrix to a nonmetric multidimensional scaling analysis, restricting the analysis to two dimensions. Figure 4 shows that five outlier groups dominate the allele-sharing distances within this data set. These outlier groups are also present in Figure 2, as discussed above, and Figure 2 and 4 resemble each other because the same fish are included in each analysis. The difference
between Figures 2 and 4 is that in Figure 4 the fish are grouped into collection year and the four treatment groups, rather than collection year and two treatment groups (hatcheryversus natural-origin).

Figure 4 does not provide useful resolution of the groups within the polygon, because the outlier groups dominate the allele sharing distances. We removed the five outlier groups from Figure 4, recalculated the allele sharing distances and subjected this new matrix to a multidimensional scaling analysis (Figure 5). Figure 5 shows separation among the 2001, 2004-2006 collections, but this separation does not necessarily indicate that within-year collections are more similar to each other than any collection is to a collection from another year. For example, the 2006 natural-origin natural spawner and the 2005 naturalorigin hatchery broodstock collections share $81 \%$ alleles, while the 2006 natural-origin natural spawner and 2006 hatchery-origin hatchery broodstock collections share $75 \%$ alleles. There does not appear to be any discernable pattern of change in allele-sharing distance among the collections relevant to pre- or post-supplementation. Although the 1989 pre-supplementation natural-origin collection appears distinct (Figure 5), the 1993 natural-origin hatchery broodstock collection appears quite similar to the 2005 and 2006 natural-origin collections (Figure 5). The 1993 natural-origin hatchery broodstock collection, although not technically pre-supplementation, is composed of fish whose ancestry cannot be traced to any Chiwawa hatchery fish. Therefore, there is no clear pattern of allele sharing change from pre-supplementation to recent collections.

There does appear to be some change in the average percentage of alleles shared within the 2001 to 2006 collections, with an increase from $74 \%$ in 2001 and 2004 to $78 \%$ and $79 \%$ in 2005 and 2006, respectively. The results provided by this analysis are consistent with the results presented in the origin and spawner data sets. That is, there are allele frequency and allele sharing differences among the collections, but analyses do not strongly suggest that these differences are a function of the supplementation program. Furthermore, there is also a weak signal that the hatchery and natural collections within the most recent years are more similar to each other than in the previous years.

Overall Genetic Variance - Although there are signals of allelic differentiation among Chiwawa River collections, there are no robust signs that these collections are substantially different from each other. We used two different analyses to measure the degree of genetic variation that exists among individuals and collections within the Chiwawa River. First, we conducted a principal component analysis using all Chiwawa samples with complete genotypes (i.e., no missing alleles from any locus). Although the first two principal component axes account for only $10.5 \%$ of the total molecular variance, a substantially greater portion of that variance is among individual fish, regardless of their identity, rather than among hatchery and natural collections (Figure 6). The variances in principal component scores among individuals are 11 and 13 times greater than the variance in scores among collections, along the first and second axes, respectively.

Second, we conducted a series of analyses of molecular variance (AMOVA) to ascertain the percentage of molecular variance that could be attributed to differences among collections. We organized these analyses to test also for differences in the hierarchical structure of the data. That is, we tested for differences among collections using the following framework:

- No organizational structure - all 25 origin-spawner collections considered separately
- Origin-spawner collections organized into 10 collection year groups
- Origin-spawner collections organized into 2 breeding location groups (hatchery versus natural)
- Origin-spawner collections organized into 2 origin groups (hatchery versus natural)
- Origin-spawner collections organized into the 4 origin-spawner groups

It is clear from this analysis that nearly all molecular variation, no matter how the data are organized, resides within a collection (Table 5). The percentage of total molecular variance occurring within collections ranged from $99.68 \%$ to $99.74 \%$. The among group variance component was limited to less than $0.26 \%$ and in all organizational structures,
except "no structure," the among group percentage was not significantly greater than zero. Furthermore, none of the organizational structures provided better resolution than "no structure" in terms of accounting for molecular variance within the data set. These results indicate that if there are significant differences among collections of Chiwawa fish, these differences account for less than one percent of the total molecular variance, and these differences cannot be attributed to fish origin or spawning location.

## Summary and Conclusions

We reject the null hypothesis that the allele frequencies of the hatchery collections equal the allele frequencies of the natural collections, which equals the allele frequency of the donor population. Furthermore, because the allele-sharing distances are not consistent within and among collections years, we also reject the second stated hypothesis discussed above. However, there is an extremely small amount of genetic variance that can be attributed to among collection differences. The allelic differentiation that does exist among collections does not appear to be a function of fish origin, spawning location, genetic drift, or collection year. Figure 5 and related statistics does suggest that hatchery and natural collections in 2005 and 2006 are more similar to each other than previous years' collections, and this would be expected in a successful integrated hatchery supplementation program.

Since each of these collection years are generally composed of four-year-old fish, the differentiation among these collections for the most part is differentiation among specific cohorts. The slightly greater percentage of alleles shared among collections that are separated in time by multiples of four years, compared with collections that are not separated in time as such, suggests that cohort differences may be the most important factor accounting for differences in allele frequencies among collections.

## Task 4: Develop a model of genetic drift.

See Task 3

# Task 5: Analyze spring Chinook population samples from the Chiwawa River and Chiwawa Hatchery from multiple generations. 

See Task 3

## Task 6: Analyze among population differences for upper Wenatchee spring Chinook.

Supplementation of the Chiwawa River spring Chinook population may affect populations within the Wenatchee River watershed other than the Chiwawa River stock. If the stray rate for Chiwawa hatchery-origin fish is greater than that for natural-origin fish, an increase in gene flow from the Chiwawa population into other populations may result. If this gene flow is high enough, Chiwawa River fish may alter the genetic structure of these other populations. Records from field observations indicate that hatchery-origin fish are present in all major spawning aggregates (A.R Murdoch, unpublished data), and these fish are successfully reproducing (Blankenship et al 2006). The intent of this task is to investigate if there have been changes to the genetic structure of the spring Chinook stocks within upper Wenatchee tributaries during the past 15-20 years, and if changes have occurred, are they a function of the Chiwawa River Supplementation Program? Therefore, we ask the following two questions:

1. Are allele frequencies within populations in the upper Wenatchee stable through time? That is, is there significant allelic differentiation among collections within upper Wenatchee populations?
2. Are the recent collections from the upper Wenatchee populations more similar to the Chiwawa population than earlier collections from the same populations?

For this task we analyzed natural spawning collections from the White River (naturalorigin), Little Wenatchee River (natural-origin), Nason Creek (natural-origin), and

Wenatchee mainstem (hatchery-origin), and hatchery collections from Leavenworth NFH and Entiat River NFH (Table 1). We also included in the analysis the natural- and hatchery-origin collections from the Chiwawa River. There are no repeated collections from Leavenworth, Entiat, Little Wenatchee, and Wenatchee mainstem (Table 1), so for many of the analyses we have limited our discussion to the Chiwawa River, White River, and Nason Creek collections. Furthermore, genetic structure of the Little Wenatchee collection, which consisted of only 19 samples, was unexpectedly quite different from the other collections. For example, the $\mathrm{F}_{\text {ST }}$ statistic measures the percent of total molecular variation that can be attributed to differences between populations. The median $\mathrm{F}_{\text {ST }}$ for all pairwise combinations of collections from all populations, except Little Wenatchee (33 populations, 528 individual $\mathrm{F}_{\mathrm{ST}}$ statistics) equals 0.010 ( $1 \%$ ), with a range of 0.000 to 0.037 (Table 6). The median $\mathrm{F}_{\text {ST }}$ for the Little Wenatchee paired with all other collections ( 33 individual $\mathrm{F}_{\text {ST }}$ statistics) equals 0.106 ( $10.6 \%$ ), with a range of 0.074 to 0.121 . The ten-fold increase in the $\mathrm{F}_{\text {ST }}$ statistic indicates that either the Little Wenatchee spring Chinook is unique among the upper Wenatchee River stocks, or this 1993 collection is somehow aberrant. Therefore, we exclude the Little Wenatchee collection from many other analyses.

Population Differentiation - Table 3 provides the levels of significance for all pairwise genic differentiation tests. Most between-collection comparisons are highly significant, with no pattern of increasing or decreasing differentiation with time, and no differences when comparisons are made with Chiwawa hatchery- versus Chiwawa natural-origin fish. For example, excluding the outlier 1996 and 1998 Chiwawa hatchery- and naturalorigin collections, Nason Creek showed highly significant allele frequency differences between the Chiwawa hatchery- and natural-origin collections at $100 \%$ and $86 \%$ of the comparisons, respectively. The same comparisons with the White River produced $100 \%$ and $93 \%$ highly significant allele frequency comparisons, respectively. Allele frequencies between Nason Creek and White River were likewise differentiated from each other.

The collection allele frequencies within the upper Wenatchee system are significantly different, and these differences do not appear to change as a function of time (Table 3). Nason Creek shows greater within-population year-to-year variation in allele frequencies than does the White River, with 47\% of the pairwise comparisons showing highly significant differences, compared with only 13\% for the White River. However, the 2005 and 2006 collections from the White River appear to be somewhat more differentiated from not only each other, but from the earlier collections from the White River.

Despite the high degree of temporal and spatial structure suggested by the genic differentiation tests, as described above for within-Chiwawa analysis (Task 3), most of the genetic variation within this data set occurs within populations, rather than between populations (Table 6). The $\mathrm{F}_{\text {ST }}$ values for most population comparisons are between 0.01 and 0.02 , indicating $1 \%$ to $2 \%$ among-population variance, with the remaining $98 \%$ to 99\% variance occurring within populations. The White River shows the highest median $\mathrm{F}_{\mathrm{ST}}$ among the natural-origin collections, equal to 0.014 , compared with 0.009 for both the Nason Creek and Chiwawa natural-origin collections. The median $\mathrm{F}_{\mathrm{ST}}$ for the Chiwawa hatchery-origin collections (0.012) was higher than that for the Chiwawa natural-origin collections.

Table 7 summarizes the information from the $\mathrm{F}_{\text {ST }}$ analyses, under five different temporal and spatial scenarios. Under all scenarios, over $99 \%$ of the molecular variance is within populations. There is significantly greater spatial structure among populations ("Origin") in 2005 and 2006 than from 1989 to 1996. That is, there appears to be more spatial structure among the Chiwawa hatchery-origin, Chiwawa natural-origin, White River, and Nason Creek now, than in 1989 to 1996, despite the potential homogenizing and cumulative effect of hatchery strays. However, we stress that the amount of molecular variance associated with the among population differences, despite being significantly greater than $0.00 \%$, is limited to only $0.43 \%$.

Allele-sharing and Nonmetric Multidimensional Scaling - As in the Chiwawa River data discussed above, we constructed an allele-sharing distance matrix and then subjected
that matrix to a multidimensional scaling analysis (Figure 7). Consistent with all previously discussed multidimensional scaling analyses, the 1996 and 1998 adult, and the 1994 smolt collections are outliers. There is clear separation between the White River collections and all other natural-origin and Chiwawa hatchery-origin collections, indicating that there are more alleles shared among the Nason Creek and Chiwawa collections, than with the White River collections. Furthermore, there is a slight separation between the Chiwawa natural-origin natural spawner collections and Nason Creek collections, suggesting different groups of shared alleles between these populations. There is more variation in the allele-sharing distances among collections involved with the Chiwawa hatchery (origin or broodstock) than any of the natural-origin collections, even if we exclude the 1994, 1996, and 1998 collections. This suggests that there is more year-to-year variation in the composition of hatchery-origin and hatchery broodstock than within natural-origin populations throughout the upper Wenatchee. All Wenatchee mainstem fish are hatchery-origin, and if these fish are from the Chiwawa Supplementation Program (rather than from Leavenworth), it is not unexpected that this collection would be plotted within the Chiwawa polygon (Figure 7).

Assignment of Individual to Populations - Finally, we conducted individual assignment tests whereby we assigned each individual fish to a population, based on a procedure developed by Rannala and Mountain (1997) (Table 8 and 9). Individual fish may be correctly assigned to the population from which they were collected, or incorrectly assigned to a different population. Incorrect assignments may occur if the fish is an actual migrant (i.e., source population different from population where collected), or because the genotype for that fish matches more closely with a population different from its source. If there are many individuals from a population incorrectly assigned to populations other than its source population, that original population is either unreal (i.e., an admixture), or there is considerable gene flow between that population and other populations. Furthermore, in assigning individuals to populations, we can either accept the assignment with the highest probability, regardless of how low that probability may be, or we can establish a more stringent criterion, such as to not accept an assignment unless the posterior probability is equal to or greater than 0.90 . This value is roughly
equal to having the likelihood of the most-likely population equal to 10 times that of the second most-likely population.

We provide a summary of the assignments in Tables 8 and 9. On average, nearly $50 \%$ of the fish are assigned incorrectly if we accept all assignments (Table 8), but the incorrect assignment rate drops to roughly $10 \%$ when we accept only those assignments with probabilities greater than 0.90 . However, with this more stringent criterion, nearly $64 \%$ of the fish go unassigned. These results indicate that the allele frequency distributions for these populations are very similar, and it would be very difficult to assign an individual fish of unknown origin to the correct population. If all fish are assigned, there is a $50 \%$ chance, overall, of a correct assignment. If you accept only those assignment with the 0.90 criterion, nearly two-thirds of the fish would be unassigned, but there is a $90 \%$ chance of correctly assigning those fish that are indeed assigned.

Of all the populations in the data set, there are fewer errors associated with assigning fish to the White River. If all fish are assigned (Table 8), $72 \%$ of those fish assigned to the White River, are actually from the White River (115 fish out of a total of 159 fish assigned to the White River). This compares to a rate of only $52 \%$ and $53 \%$ for Nason Creek and Chiwawa natural-origin, respectively, and $60 \%$ for the Chiwawa hatcheryorigin collections. With the 0.90 criterion (Table 9), $89 \%$ of the fish assigned to the White River, are actually from the White River, compared with $70 \%$ and $65 \%$ for Nason Creek and Chiwawa natural origin, respectively, and $81 \%$ for the Chiwawa hatchery origin.

When all fish are assigned, most of the incorrectly assigned fish from Nason Creek and White River are assigned to Chiwawa River, at roughly equal frequencies to the hatcheryand natural-origin populations. Incorrectly assigned fish to other populations occur at a slightly higher rate in Nason Creek than in the White River. However, when only those fish meeting the 0.90 criterion are assigned (Table 9), incorrectly assigned fish from Nason Creek are distributed among White and Chiwawa Rivers, as well as Leavenworth NFH, and the Entiat NFH. Mis-assignment to the Chiwawa hatchery-origin was the
highest among the Nason Creek collections, equal to nearly $14 \%$. This contrasts with the White River where mis-assignments do not exceed $7 \%$ anywhere, and there is a roughly even distribution of mis-assignments among Nason Creek and Chiwawa River collections.

Summary and Conclusions - There is little geographic or temporal structure among populations within the upper Wenatchee systems. Among population molecular variance is limited to $1 \%$ or less. The little variance that can be attributed to among populations indicates that the White River is more differentiated from the Chiwawa and Nason populations than these populations are from each other. Furthermore, although we cannot rule out a hatchery effect on the Nason Creek and White River populations, there is no indication there has been any temporal changes in allele frequencies within these populations that can be attributed directly to the Chiwawa River Supplementation Program. In fact, Table 7 weakly suggests that there is more differentiation among these populations now, than there was before or at the early stages of Chiwawa supplementation.

Therefore, returning to our two original questions, there are significant differences in allele frequencies among collections within populations, and among populations within the upper Wenatchee spring Chinook stocks. However, these differences account for a very small portion of the overall molecular variance, and these populations overall are very similar to each other. There is no evidence that the Chiwawa River Supplementation Program has changed the allele frequencies in the Nason Creek and White River populations, despite the presence of hatchery-origin fish in both these systems. Finally, of all the populations within the Wenatchee River, the White River appears to be the most distinct. Yet, this distinction is more a matter of detail than of large significance, as the median $\mathrm{F}_{\text {ST }}$ between White River collections and all other collections (except the Little Wenatchee) is less than $1.5 \%$ among population variance.

## Task 7: Calculate the inbreeding effective population size using demographic data for each sample year, and document the ratio of census to effective size.

This analysis was completed by Williamson et al. (submitted).

## Task 8: Calculate LD $\mathrm{N}_{\mathrm{b}}$ using genetic data for each sample year, and document the ratio of census to effective size.

We report $\mathrm{N}_{\mathrm{e}}$ estimated for the Chiwawa River collections based on the bias correction method of Waples (2006) implemented in LDNe (Do and Waples unpublished). $\mathrm{N}_{\mathrm{e}}$ estimates based on LD are best interpreted as the effective number of breeders $\left(\mathrm{N}_{\mathrm{b}}\right)$ that produced the sample (Waples 2006).

For collections categorized by spawning location (i.e., hatchery broodstock or natural), estimates of $\mathrm{N}_{\mathrm{b}}$ are shown in Table 10. Considering the hatchery broodstock, $\mathrm{N}_{\mathrm{b}}$ estimates range from 30.4 (1996) to 274.3 (2005). To obtain $\mathrm{N}_{\mathrm{e}} / \mathrm{N}$ ratios, the $\mathrm{N}_{\mathrm{b}}$ estimate is multiplied by four (i.e., mean generation length) and divided by the total in river (i.e., NOS [natural-origin spawners] plus HOS [hatchery-origin spawners]) census data from four years prior (i.e., major cohort; see Table 2). The observed $\mathrm{N}_{\mathrm{e}} / \mathrm{N}$ ratios for the broodstock collections range from $11 \%$ to $54 \%$ of the census estimate, excluding the 2000 collection which is $106 \%$. A ratio greater than one is possible under special circumstances, and certain artificial mating schemes within hatcheries can inflate $\mathrm{N}_{\mathrm{e}}$ above N ; yet, it is unknown if this is the case for this collection. While no direct comparisons are possible, the $\mathrm{N}_{\mathrm{b}}$ estimates reported by Williamson et al. (submitted) for Chiwawa broodstock collections from 2000 - 2003 are similar in magnitude to our estimates. For Chiwawa natural spawner collections, the $\mathrm{N}_{\mathrm{b}}$ estimates range from 5.2 (1989) to 231.5 (2005), with observed $\mathrm{N}_{\mathrm{e}} / \mathrm{N}$ ratios of $22 \%-48 \%$ of the census estimate.

## Task 9: Calculate $\mathbf{N}_{\mathrm{b}}$ using the temporal method for multiple samples from the same location.

Estimates of effective number of breeders $\left(\mathrm{N}_{\mathrm{b}}\right)$ derived from Waples' (1990) temporal method are shown in Tables 11-13. Eight collection years were used for the Chiwawa broodstock collections (Table 11). The harmonic mean of all pairwise estimates of $\mathrm{N}_{\mathrm{b}}$ ( $\tilde{\mathrm{N}}_{\mathrm{b}}$ ) was 269.4. This estimate is the contemporary $\mathrm{N}_{\mathrm{e}}$ for Chiwawa broodstock collections. For the five collection years of Chiwawa in-river spawners (Table 12), the estimated $\tilde{\mathrm{N}}_{\mathrm{b}}=224.2$. This estimate is the contemporary $\mathrm{N}_{\mathrm{e}}$ for Chiwawa River natural spawner collections. Since the Chiwawa Supplementation Program is integrated by design, we also performed another estimation of $\mathrm{N}_{\mathrm{e}}$ using composite hatchery and natural samples. There are paired samples from 2004-2006. We combined genetic data for hatchery (HOS) and natural (NOS) origin fish from 2004-2006 to create a single Chiwawa River natural spawner sample for each year. The three composite samples from 2004 - 2006 were then analyzed using the temporal method (Table 13), resulting in a $\tilde{\mathrm{N}}_{\mathrm{b}}$ $=386.8$. This estimate is the contemporary $\mathrm{N}_{\mathrm{e}}$ for Chiwawa River.

Williamson et al. (submitted) estimated $\mathrm{N}_{\mathrm{e}}$ using Waples' (1990) temporal method for Chinook captured in 2004 and 2005, and used age data to decompose brood years into consecutive cohorts from 2000-2003. They report for Chiwawa broodstock a $\tilde{\mathrm{N}}_{\mathrm{b}}=$ 50.4. This estimate is not similar to our Chiwawa broodstock estimate. However, if we analyze the hatchery-origin Chinook only, our estimate is $\tilde{\mathrm{N}}_{\mathrm{b}}=80.1$ for collection years 1989 - 2006 (data not shown). Williamson et al. (submitted) report for Chiwawa naturally spawning Chinook a $\tilde{\mathrm{N}}_{\mathrm{b}}=242.7$, which is slightly higher than our estimate for in-river spawners from 1989-2006, but lower than our estimate from combined NOS and HOS Chinook from 2004-2006 collection years.

## Task 10: Use available data and the Ryman-Laikre and Wang-Ryman models to determine the expected change of $\mathbf{N}_{\mathrm{e}}$ for natural spring Chinook salmon in the Wenatchee River due to hatchery operation.

$\mathrm{N}_{\mathrm{e}}$ is generally thought to be between 0.10 and 0.33 of the estimated census size (Bartley et al. 1992; RS Waples pers. comm.). We used this range to generate an estimate of $\mathrm{N}_{\mathrm{e}}$ for Chiwawa natural spawners prior to hatchery operation. For brood years 1989 - 1992, the arithmetic mean census size was $\mathrm{N}=962.7$ (Table 2), resulting in an estimated $\mathrm{N}_{\mathrm{e}}$ ranging from 96.3 - 317.7. The contemporary estimate of $\mathrm{N}_{\mathrm{e}}$ calculated using genetic data for the Chiwawa in-river spawners is $\mathrm{N}_{\mathrm{e}}=224.2$ (Table 12), falling in the middle of the pre-hatchery range. The $\mathrm{N}_{\mathrm{e}} / \mathrm{N}$ ratio calculated using 224.2 and the arithmetic census of NOS Chinook from 1989 - 2005 is 0.42 . A more appropriate contemporary $\mathrm{N}_{\mathrm{e}}$ to compare with the pre-hatchery estimate (i.e., $96.3-317.7$ ) is the combined NOS and HOS estimate from natural spawners, since the supplementation program is integrated. As discussed above, the contemporary estimate of $\mathrm{N}_{\mathrm{e}}$ calculated using genetic data for Chiwawa NOS and HOS Chinook is $\mathrm{N}_{\mathrm{e}}=386.8$ (Table 13), which is slightly larger than the pre-hatchery range, suggesting the $\mathrm{N}_{\mathrm{e}}$ has not declined during the period of hatchery operation. The $\mathrm{N}_{\mathrm{e}} / \mathrm{N}$ ratio calculated using 386.8 and the arithmetic census of NOS and HOS Chinook from 1989 - 2005 is 0.40 . These results suggest the Chiwawa Hatchery Supplementation Program has not resulted in a smaller $\mathrm{N}_{\mathrm{e}}$ for the natural spawners from the Chiwawa River.

Williamson et al. (submitted) argued that since their combined (i.e., broodstock and natural) $\mathrm{N}_{\mathrm{e}}$ estimate was lower than the naturally spawning estimate, the supplementation program likely had a negative impact on the Chiwawa River $\mathrm{N}_{\mathrm{e}}$. We disagree with this interpretation of these data. Since the natural spawning component is mixed hatchery and natural ancestry, the $\mathrm{N}_{\mathrm{e}}$ estimates from natural spawning data are the results that bear on possible hatchery impacts. The census data show the population declined in the mid 1990's and rebounded by 2000 (Table 2). This trend is reflected in the $\mathrm{N}_{\mathrm{e}}$ results, as shown above, and Williamson et al. (submitted) clearly show in their Table 4 the $\mathrm{N}_{\mathrm{e}}$ was lower in $2000\left(\mathrm{~N}_{\mathrm{e}}=989\right)$ than it was in $1992\left(\mathrm{~N}_{\mathrm{e}}=2683\right)$. Yet, the important comparison
they make in our view was the natural spawning $\mathrm{N}_{\mathrm{e}}$ versus the natural only component $\mathrm{N}_{\mathrm{e}}$ (i.e., hypothetically excluding hatchery program). Williamson et al. (submitted) report the 1989 - $1992 \mathrm{~N}_{\mathrm{e}}$ estimated from naturally spawning Chinook (i.e., NOS and HOS integrated) was essentially the same as the natural only component estimate, 2683 and 2776, respectively. This result is not surprising since no HOS fish were present between 1989 - 1992. They also report that the $1997-2000 \mathrm{~N}_{\mathrm{e}}$ estimated from naturally spawning Chinook (i.e., NOS and HOS integrated) was $\mathrm{N}_{\mathrm{e}}=989$, while the natural-origin estimate of $\mathrm{N}_{\mathrm{e}}$ in $1997-2000$ was $\mathrm{N}_{\mathrm{e}}=629$. Since the natural-origin estimate of 629 is lower than 989 , the $\mathrm{N}_{\mathrm{e}}$ estimate from all in-river spawners, we argue that their analysis of demographic data show the $\mathrm{N}_{\mathrm{e}}$ estimated from naturally spawning Chinook (i.e., NOS and HOS integrated) is larger only if the hatchery Chinook in the river are ignored.

## Task 11: Use individual assignment methods to determine the power of self-assignment for upper Wenatchee River tributaries.

See "Assignment of Individual to Populations" in Task 6

## Conclusions

Has the Chiwawa Hatchery Supplementation Program succeeded at increasing the census size of the target population while leaving genetic integrity intact? This is an important question, as hatcheries can impact natural populations by reducing overall genetic diversity (Ryman and Laikre 1991), reducing the fitness of the natural populations through relaxation of selection or inadvertent positive selection of traits advantageous in the hatchery (Ford 2002; Lynch and O’Hely 2001), and by reducing the reproductive success of natural populations (McLean et al. 2003). The census data presented here show that the current natural spawning census size is similar to the pre-supplementation census size. Despite large numbers of hatchery-origin fish on the Chiwawa River spawning grounds, the genetic diversity of the natural-origin collections appear unaffected by the supplementation program; heterozygosities are high, and contemporary $\mathrm{N}_{\mathrm{e}}$ is similar (perhaps slightly higher) than pre-supplementation $\mathrm{N}_{\mathrm{e}}$. We did find
significant year-to-year differences in allele frequencies in both the origin and spawner datasets, but these differences do not appear to be related to fish origin, spawning area, or genetic drift. However, we do suggest that cohort differences may be the most important factor accounting for differences in allele frequencies among collections.

The main objective of this study was to determine the potential impacts of the hatchery program on natural spring Chinook in the upper Wenatchee system. We did this by analyzing temporally replicated collections from the Chiwawa River, and by comparing genetic diversity prior to the presumed effect of the Chiwawa Hatchery Supplementation Program, with contemporary collections. We report that the genetic diversity present in the Chiwawa River is unchanged (allowing for differences among cohorts) from 1989 2006, and the contemporary estimate of the effective population size $\left(\mathrm{N}_{\mathrm{e}}\right)$ using genetic data is approximately the same as the $\mathrm{N}_{\mathrm{e}}$ estimate extrapolated from 1989 - 1992 census data (i.e., pre-hatchery collection years). We observed substantial genetic diversity, with heterozygosities $\sim 80 \%$ over thirteen microsatellite markers. Yet, temporal variation in allele frequencies was the norm among temporal collections from the same populations (i.e., location). The genetic differentiation of replicated collections from the same population is likely the result of salmon life history in this area, as four-year-old Chinook comprise a majority of returns each year. The genetic tests are detecting the differences of contributing parents for each cohort. An important point related to the temporal variation, is that the hatchery broodstock is composed in part of the natural origin Chinook from the Chiwawa River. When we compared the genetic data (within a collection year) for Chinook brought into the hatchery as broodstock with the Chinook that remained in the river (years 2001, 2004 - 2006), there was a trend of decreasing statistical differences in allele frequencies from 2001 to 2004, and no differences were detected for 2005 and 2006. While the replicated collections may have detectable differences in allele frequencies, those differences reflect actual differences in cohorts, not the result of hatchery operations, and the hatchery broodstock collection method captures the differences in returning Chiwawa River spring adults each year. We conclude from these results that the genetic diversity of natural spring Chiwawa Chinook has been maintained during the Chiwawa Hatchery Supplementation Program.

We observe slight, but statistically significant population differentiation between Chiwawa River, White River, and Nason Creek collections. Murdoch et al (2006) and Williamson et al. (submitted) also observed population differentiation between Chiwawa River, White River, and Nason Creek collections. Yet, $99.3 \%$ of the genetic variation observed was within samples, very little variance could be attributed to population differences (i.e., population structure). The AMOVA analysis and poor individual assignment results suggest the occurrence of gene flow among Wenatchee River locations or a very recent divergence of these groups. While Murdoch et al. 2006 did not perform an AMOVA analysis, their $\mathrm{F}_{\text {ST }}$ results provide comparable data to our amongpopulation results. Murdoch et al. 2006 report $\mathrm{F}_{\text {ST }}$ ranging from $2 \%-3 \%$ for pairwise comparisons between of Chiwawa, White, and Nason River collections. Since $\mathrm{F}_{\text {ST }}$ is an estimate of among-sample variance, these results also imply a majority of the genetic variance (i.e., $97 \%-98 \%$ ) resides within collections. To provide further context for the magnitude of these variance estimates, we present the among-group data from Murdoch et al. 2006 comparing summer-run and spring-run Chinook from the Wenatchee River. They report that approximately $91 \%$ of observed genetic variance is within-collection for comparisons between collections of summer- and spring-run Chinook. Ultimately, the information provided by this and other reports will be incorporated into the management process for Wenatchee River Chinook. However, we would like to emphasize that the application of these genetic data to management is more about the goals related to the distribution of genetic diversity in the future than specific data values reported. If Chinook are collected at Tumwater Dam instead of within the upper Wenatchee River tributaries, a vast majority of the genetic variation present in the basin would be captured, although any differences among tributaries would be mixed. Alternatively, management policies could be crafted to promote and maintain the among-group genetic diversity that genetic studies consistently observe to be non-zero within the Wenatchee River.

We agree with Murdoch et al. (2006) that it appears hatchery Chinook are not contributing to reproduction in proportion to their abundance. Additionally, if the total census size (i.e., NOS and HOS combined) within the Chiwawa River does not continue
to increase, genetic diversity may decline within this system, given the smaller $\mathrm{N}_{\mathrm{e}}$ within the hatchery-origin collections compared with the natural-origin collections.

## Acknowledgements

We would like to thank Denise Hawkins, Craig Busack, and Cheryl Dean for helpful comments regarding this project. This project was funded by Chelan County PUD and the Washington State General Fund.

Figure 1. Conceptual process for evaluating potential changes in genetic variation in the Chiwawa naturally produced populations as a result of the supplementation hatchery programs (From Murdoch and Peven 2005).

Figure 2. Multidimensional scaling plot from an allele-sharing distance matrix calculated from the Chiwawa data set organized by fish origin (i.e., hatchery versus natural). The red arrows connect consecutive hatchery-origin collections starting with the first adult collection (1996) and ending with the 2006 collection (see Table 1 for collection years).

Figure 3. Relationships between the time interval in years and allele sharing distances, with each circle representing the pairwise relationship between two Chiwawa collections. Separate regression lines for the natural- and hatchery-origin collections. The slope for the natural-origin collection is not significantly different from zero ( $\mathrm{p}=0.1483$ ), while the slope for hatchery-origin collection is significantly greater than zero ( $\mathrm{p}=0.0254$ ) indicating a positive relationship between time interval and allele sharing distance.

Figure 4. Multidimensional scaling plot from an allele-sharing distance matrix calculated from the Chiwawa data set organized by four treatment groups, as discussed in the text. Each circle represents a single collection within each of the four treatment groups, and the polygon encloses all groups that are not outliers. Each outlier group is specifically labeled.

Figure 5. As in Figure 4, but allele-sharing distance matrix recalculated without the five outlier groups shown in Figure 4. Polygons group together treatment groups from the same collection year. Dates associated with symbols also refer to collection year. Collection years 2004-2006 included all four treatment groups, while collection year 2001 did not include a hatchery-origin natural spawner group. Legend is read as follows: Open circles refer to hatchery-origin hatchery spawner group, while filled box refers to natural-origin hatchery spawner group, and so on.

(5.3\%)

Figure 6. Principal component (PC) analysis of individual fish from the Chiwawa River. Only fish with complete microsatellite genotypes were included in the analysis ( $\mathrm{n}=757$ ). Open circles are the PC scores for individual fish, and the filled circles are the centroids (bivariate means) for each of the 25 groups discussed in the text. PC axes 1 and 2 account for only $10.5 \%$ of the total molecular variance.

Figure 7. Multidimensional scaling plot from an allele-sharing distance matrix calculated from the Chiwawa origin data set and all other non-Chiwawa collections, except Little Wenatchee River. Legend is read with abbreviations beginning with origin and then spawning location. $\mathrm{H}=$ hatchery, $\mathrm{N}=$ natural, and $\mathrm{S}=$ smolts. Polygons with solid lines enclose the naturalorigin natural spawner collections from each population (i.e., river). The polygon with the dotted lines enclose all Chiwawa collections, except for the five outlier collections, as discussed in text.

Table 1 Summary of within population genetic data. Chiwawa collection data are summarized in A) by origin of the sample (i.e., clipped vs. non-clipped). All collection data are summarized in B) by spawning location (i.e., hatchery broodstock or on spawning grounds). Hz is heterozygosity, HWE is the statistical significance of deviations from Hardy-Weinberg expectations $(*=0.05, * *=0.01$, and $* * *=0.001$ ), LD is the proportion of pairwise locus tests (across all populations) exhibiting linkage disequilibrium (bolded values are statistically significant), and the last column is mean number of alleles per locus.

|  | Sample <br> size | Gene <br> Diversity | Observed <br> Hz | HWE | $\mathrm{F}_{\text {IS }}$ | LD | Mean \# <br> Alleles |

Table 3 Levels of significance for pairwise tests of genic differentiation among all hatchery- and natural-origin collections used in this analysis. HS = highly significant ( $\mathrm{P}<0.000095$; the Bonferroni corrected p-value for an alpha $=0.05$ ); * $=\mathrm{P}<0.05$ (nominal critical value for most statistical test); - = $>0.05$ (not significant). A significant result between pairs of populations indicates that the allele frequencies between the pair are significantly different. Results are read by comparing the collections along the rows to collections along columns. The top block for each section is a symmetric matrix, as it compares collections within the same group.

Table 4 Probabilities (above diagonal) and levels of significance (below diagonal) for pairwise tests of genic differentiation among all Chiwawa hatchery broodstock and Chiwawa natural spawner collections used in this analysis. HS = highly significant ( $\mathrm{P}<0.000476$; the Bonferroni corrected pvalue for an alpha $=0.05$ ); * $=\mathrm{P}<0.05$ (nominal critical value for most statistical test); $-=\mathrm{P}>0.05$ (considered not significant). A significant result between pairs of populations indicates that the allele frequencies between the pair are significantly different. Pairwise comparisons between the hatchery broodstock and natural spawner collections from 2001, 2004, 2005, and 2006, respectively, are highlighted.

Table 5 Analysis of molecular variance (AMOVA) for the Chiwawa collections, showing the partition of molecular variance into (1) within collections, (2) among collections but within group, and (3) among group components. Each column in the table represents a separate analysis testing for differences under a different spatial or temporal hypothesis. The different analyses are grouped together in a single table for comparisons. The values within the table are percentages and the parenthetical values are P -values, or probabilities, associated with that percentage. P values greater than 0.05 indicate that the percentage is not significantly different from zero. For example, when collections are organized by hatchery- versus natural-origin ("Origin" - fourth column), $0.11 \%$ of the molecular variance is attributed to among group (i.e., hatchery- versus natural-origin), which is not significantly different from zero. No collections (first column) indicates no organization or grouping among all collections, and the among-group percentage is equal to the $\mathrm{F}_{\mathrm{ST}}$ for the entire data set.

|  | No Structure | Collection <br> Year | Spawning <br> Location | Origin | Origin- <br> Spawning <br> Location |
| :--- | :---: | :---: | :---: | :---: | :---: |
| Among Groups | 0.26 | 0.20 | 0.05 | 0.11 | 0.11 |
|  | $(0.00)$ | $(0.43)$ | $(0.48)$ | $(0.15)$ | $(0.06)$ |
| Among collections - | - | 0.08 | 0.24 | 0.21 | 0.18 |

|  |  | 99.72 | 99.71 | 99.68 | 99.71 |
| Within collections | 99.74 | $(0.00)$ | $(0.00)$ | $(0.00)$ | $(0.00)$ |

Table $6 \mathrm{~F}_{\text {ST }}$ values for all pairwise combinations of populations. Each $\mathrm{F}_{\text {ST }}$ is the median value for all pairwise combinations of collections within each population (the number of collections within each population is shown parenthetically next to each population name on each row). For example, the $\mathrm{F}_{\text {ST }}$ for the Chiwawa hatchery versus the White River ( 0.019 ) is the median value of 54 pairwise comparisons. The bold values along the center diagonal are the median $\mathrm{F}_{\text {ST }}$ values within each collection. For those populations with only one collection, the diagonal value was set at 0.000 .

Table 8 Individual assignment results reported are the numbers of individuals assigned to each population using the partial Bayesian criteria of Rannala and Mountain (1997) and a "jack-knife" procedure (see Methods). The population with the highest posterior probability is considered the stock of origin (i.e., no unassigned individuals). Individuals from each population are assigned to specific populations (along rows). Bold values indicate correct assignment back to population of origin. Individuals assigned to a population are read down columns. For example, of the 595 individuals from Chiwawa hatchery origin, 134 individuals were assigned to Chiwawa natural origin (reading across). Of the 511 individuals assigned to Chiwawa natural origin (reading down), 60 were from Nason Creek.

| Population | Total | Unassigned | $\mathbf{1}$ | $\mathbf{2}$ | $\mathbf{3}$ | $\mathbf{4}$ | $\mathbf{5}$ | $\mathbf{6}$ | $\mathbf{7}$ | $\mathbf{8}$ |
| :--- | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| 1) Chiwawa Hatchery | 595 | 0 | $\mathbf{3 7 1}$ | 134 | 2 | 16 | 0 | 45 | 15 | 12 |
| 2) Chiwawa Natural | 501 | 0 | 156 | $\mathbf{2 6 9}$ | 4 | 5 | 0 | 42 | 9 | 16 |

|  |  |  |  |  |  |  |

Table 11 Summary of output from program SALMONNb and data for eight Chiwawa broodstock collections from Wenatchee River. For each pairwise comparison of samples $i$ and $j, \widetilde{\mathrm{~S}}$ is the harmonic mean sample size, $n$ is the number of independent alleles used in the comparison, $\hat{\mathrm{N}}_{\mathrm{b}(\mathrm{i}, \mathrm{j})}$ are the pairwise estimates of $\mathrm{N}_{\mathrm{b}}$, and $\operatorname{Var}\left[\hat{\mathrm{N}}_{\mathrm{b}(\mathrm{i}, \mathrm{j})}\right]$ is the variance of $\hat{\mathrm{N}}_{\mathrm{b}(\mathrm{i}, \mathrm{j})} . \widetilde{\mathrm{N}}_{\mathrm{b}}$ is the harmonic mean of the $\hat{\mathrm{N}}_{\mathrm{b}(\mathrm{i}, \mathrm{j})}$. Alleles with a frequency below 0.05 were excluded from the analysis to reduce potential bias.

| Year | 1993 | 1996 | 1998 | 2000 | 2001 | 2004 | 2005 | 2006 |
| :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- |

Pairwise $\widetilde{\mathrm{S}}$ (above diagonal) and $n$ (below diagonal):

| 1993 | - | 24.5 | 42.5 | 66.4 | 67.2 | 57.2 | 64.6 | 70.3 |

#### Abstract

We investigated genetic relationships among temporally replicated collections of summer Chinook from the Wenatchee River, Methow River, and Okanogan River in the upper Columbia River basin. Samples from the Eastbank Hatchery Wenatchee stock, Eastbank Hatchery - MEOK stock, and Wells Hatchery were also included in the analysis. Samples of natural- and hatchery-origin summer Chinook were analyzed and compared to determine if the supplementation program has had any impacts to the genetic structure of these populations. We also calculated the effective number of breeders for collection locations of natural- and hatchery-origin summer Chinook from 1993 and 2008. In general, population differentiation was not observed among the temporally replicated collection locations. A single collection from the Okanogan River (1993) was the only collection showing statistically significant differences. The effective number of breeders was not statistically different from the early collection in 1993 in comparison to the late collection in 2008. Overall, these analyses revealed a lack of differentiation among the temporal replicates from the same locations and among the collection from different locations, suggesting the populations have been homogenized or that there has been substantial gene flow among populations. Additional comparisons among summer-run and fall-run Chinook populations in the upper Columbia River were conducted to determine if there was any differentiation between Chinook with different run timing. These analyses revealed pairwise $F_{\text {ST }}$ values that were less than 0.01 for the collections of summer Chinook to collections of fall Chinook from Hanford Reach, lower Yakima River, Priest Rapids, and Umatilla. Collections of fall Chinook from Crab Creek, Lyons Ferry Hatchery, Marion Drain, and Snake River had pairwise FsT values that were higher in comparison to the collections of summer Chinook. The consensus clustering analysis did not provide good statistical support to the groupings, but did show relationships among collections based on geographic proximity. Overall the summer and fall run Chinook that have historically been

spawned together were not differentiated while fall Chinook from greater geographic distances were differentiated.

## Introduction

The National Marine Fisheries Service (NMFS) recognizes 15 Evolutionary Significant Units (ESU) for Chinook salmon (Oncorhynchus tshawytscha) (Myers et al. 1998). The summer Chinook from the upper Columbia River are included in the Upper Columbia River Summer- and Fall-Run ESU, which encompasses all late-run (summer and fall), ocean-type Chinook salmon from the mainstem Columbia River and its tributaries (excluding the Snake River) between Chief Joseph and McNary Dams (Waknitz et al. 1995). Waknitz et al. (1995) concluded that due to high total abundance this ESU was not likely to become at risk from extinction. Yet, a majority of natural spawning activity was in the vicinity of Hanford Reach, and it was unclear whether natural production was selfsustaining given the vast summer Chinook artificial propagation efforts (Waknitz et al. 1995). Additionally, the Biological Review Team expressed concern about potential consequences to genetic and life-history traits from an increasing contribution of hatchery fish to total spawning escapement (Waknitz et al. 1995).

Artificial propagation of ocean-type Chinook from the middle/upper Columbia has been continuous since the implementation of the Grand Coulee Fish Maintenance Project (GCFMP) in 1939 (Myers et al. 1998). The US Fish and Wildlife Service established three hatchery programs for summer/fall Chinook during the GCFMP, Leavenworth NFH, Entiat NFH, and Winthrop NFH. The Washington Department of Fisheries (now Washington Department of Fish and Wildlife) followed with hatchery programs at Rocky Reach (1964), Wells Dam (1967), Priest Rapids (1974), and Eastbank (1990) facilities. Currently, only Leavenworth NFH and Winthrop NFH are not producing summer/fall Chinook. Entiat NFH has resumed production of summer/fall Chinook (Wells FH Stock) in 2009 and released their first yearling summer Chinook smolts in 2010. Since

1941, over 200 million ocean-type Chinook salmon have been released into the middle Columbia River Basin (Myers et al. 1998). Initially, the hatchery programs differentiated between early returning fish (i.e., stream-type) and later returning fish (i.e., ocean-type), but no distinction was made regarding the "summer" and "fall" components of the ocean-type stocks (Waknitz et al. 1995). Therefore, all Chinook salmon now migrating above Rock Island Dam descend from not only a mixture between different stocks from the basin, but also a mixture between the endemic summer and fall life histories. While hatchery protocols have been modified of late to maintain discreet summer and fall Chinook hatchery stocks (Utter et al. 1995; see also HGMP), physical evidence and genetic data suggests that summer and fall Chinook may have become homogenized. During the 1970's and 80's, given coded-wire tag recoveries, summer-run Chinook originating from above Rock Island Dam were believed to have spawned extensively with Hanford Reach and Priest Rapids Hatchery fish (Chapman 1994). Stuehrenberg et al. (1995) reported that $10 \%$ of their radio tagged summer Chinook were occupying typical fall-run spawning habitat on the mainstem Columbia river, and $25 \%$ of fall fish released from Priest Rapids were recovered as summers at (or above) Wells Hatchery. Genetic data reported by Marshall et al. (1995) and Waknitz et al. (1995) corroborate these observations, as genetic distances observed between summer and fall Chinook within the Upper Columbia River Summer- and Fall-Run ESU were essentially zero.

In response to the need for evaluation of the supplementation hatchery programs, both a monitoring and evaluation plan (DCPUD 2005; Murdoch and Peven 2005) and the associated analytical framework (Hays et al. 2006) were developed for the Habitat Conservation Plan's Hatchery Committee through the joint effort of the fishery co-managers (CCT, NMFS, USFWS, WDFW, and YN) and Chelan County and Douglas County PUDs. These reports outline 10 objectives to be applied to various species assessing the impacts of hatchery operations mitigating the operation of Wells, Rocky Reach, and Rock Island hydroelectric projects. The present monitoring and evaluation study plan differs
in scope from previous monitoring and evaluation projects proposed by WDFW Molecular Genetics Lab, in that it does not investigate a single watershed, but instead will encompass all summer Chinook stocks from the upper Columbia River including the three supplementation (Wenatchee, Methow, and Okanogan) and the harvest augmentation program (Wells summer Chinook). The objectives of this study were to determine if genetic diversity, population structure, and effective population size have changed in natural spawning populations as a result of the hatchery programs.

## Materials and Methods

## Collections

A total of 2,416 summer Chinook were collected from tributaries in the upper Columbia River basin and were analyzed (Table 1). Two collections of naturalorigin summer Chinook from 1993 (prior to the supplementation program) were taken from the Wenatchee River Basin and were compared to collections of hatchery and natural-origin from 2006 and 2008 that were post-supplementation. Two pre-supplementation collections from the Methow River (1991 and 1993) were compared to post-supplementation collections from 2006 and 2008. Three pre-supplementation collections from the Okanogan River Basin (1991, 1992, and 1993) were compared with post-supplementation collections from 2006 and 2008. A collection of natural-origin summer Chinook from the Chelan River was also analyzed. Additionally, hatchery collections from Eastbank Hatchery (Wenatchee and MEOK stock) and Wells Hatchery were analyzed and compared to the in-river collections. Summer Chinook data (provided by the USFWS) from the Entiat River was also used for comparison. Lastly, data from eight collections of fall Chinook was compared to the collections of summer Chinook.

## Laboratory Analyses

All laboratory analyses were conducted at the WDFW Genetics Laboratory in Olympia, Washington. Genomic DNA was extracted by digesting a small piece of fin tissue using the nucleospin tissue kits obtained from Macherey-Nagel following the recommended conditions in the user manual. Extracted DNA was eluted with a final volume of $100 \mu \mathrm{~L}$.

Genotype information was generated using thirteen microsatellite markers following standard laboratory protocols and analysis methods. Descriptions of the loci assessed in this study and polymerase chain reaction (PCR) conditions are given in Table 2. PCR reactions were run with a thermal profile consisting of: denaturation at $95^{\circ} \mathrm{C}$ for 3 min , denaturation at $95^{\circ} \mathrm{C}$ for 15 sec , anneal for 30 sec at the appropriate temperature for each locus (Table 2), extension at $72^{\circ} \mathrm{C}$ for 1 min , repeat cycle (steps 2-4), final extension at $72^{\circ} \mathrm{C}$ for 30 minutes. PCR products were then processed with an ABI-3730 DNA Analyzer. Genotypes were visualized with a known size standard (GS500LIZ 3730) using GENEMAPPER 3.7 software. Alleles were binned in GENEMAPPER using the standardized allele sizes established for the Chinook GAPS dataset (Seeb et al. 2007).

## Within-collection Statistical Analyses

Allele frequencies were calculated with CONVERT (version 1.3, Glaubitz 2003). Hardy-Weinberg proportions for all loci within each collection were calculated using GENEPOP (version 3.4, Raymond and Rousset 1995). Heterozygosity (observed and expected) was computed for each collection group using GDA (Lewis and Zaykin 2001).

Allelic richness and $\mathrm{F}_{\text {IS }}$ (Weir and Cockerham 1984) inbreeding coefficient were calculated using FSTAT (version 2.9.3.2, Goudet 2001). Linkage disequilibrium for each pair of loci in each collection was calculated using GENEPOP v 3.4 (10,000 dememorizations, 100 batches, and 5,000 iterations per batch). Pairwise estimates of genetic differentiation between collection groups were
calculated using GENEPOP (version 3.4, Raymond and Rousset 1995).
Statistical significance for the tests of Hardy-Weinberg proportions, linkage disequilibrium, and genotypic differentiation was evaluated using a Bonferroni correction of $p$-values to account for multiple, simultaneous tests (Rice 1989).

## Between-collection Statistical Analyses

Pairwise $\mathrm{F}_{\text {ST }}$ estimates were computed to examine population structure among collections using GENETIX (version 4.03, Belkhir et al. 2001). This estimate uses allelic frequency data and departures from expected heterozygosity to assess differences between pairs of populations.

We used PHYLIP (version 3.5c, Felsenstein 1993) to calculate Cavalli-Sforza and Edwards (1967) pairwise chord distances between collections. Bootstrap calculations were performed using SEQBOOT followed by calculations of genetic distance using GENDIST. The NEIGHBOR-JOINING method of Saitou and Nei (1987) was used to generate the dendrograms and CONSENSE to generate a final consensus tree from the 1,000 replicates. The dendrogram generated in PHYLIP was plotted as an unrooted radial tree using TREEVIEW (version 1.6.6, Page 1996).

## Effective Number of Breeders

The effective number of breeders $\left(\mathrm{N}_{\mathrm{b}}\right)$ was estimated for pre- and postsupplementation program collections (where possible) to investigate whether hatchery programs had affected that genetic metric over the operational period. Wang (2009) derived an equation for effective size $\left(\mathrm{N}_{\mathrm{e}}\right)$ as a function of the frequency of nested full-sib and half-sib families in a random collection of individuals.

$$
\begin{equation*}
\frac{1}{N_{e}}=\frac{1+3 \alpha}{4}\left(Q_{1}+Q_{2}+2 Q_{3}\right)-\frac{\alpha}{2}\left(\frac{1}{N_{1}}+\frac{1}{N_{2}}\right) \tag{equation10}
\end{equation*}
$$

Where $\alpha$ is a measure of the deviation of genotype frequencies from HardyWeinberg expectation (equivalent to Wright's (1969) $\mathrm{F}_{\text {IS }}$ ), $Q_{i}$ are the probabilities that a pair of offspring are paternal half sibs, maternal half sibs, or full sibs, respectively, and $\mathrm{N}_{1}$ and $\mathrm{N}_{2}$ are the number of male and female parents that generation, respectively. Genetic parameters (i.e., sibship distributions) were estimated for summer Chinook collections using algorithms implemented in COLONY (Jones and Wang 2009). To be clear, Wang's (2009) method as implemented here will estimate $N_{b}$, given multi-locus genotypes from each collection were partitioned by brood year for this analysis. To obtain an estimate of $N_{e}$ each $N_{b}$ value must be multiplied by the mean generation time of that population.

## Results

## Collections

A total of 2,350 individuals from 32 collections of temporally replicated samples (six locations) were analyzed (Table 1). Temporally replicated collections of hatchery and natural-origin samples were from the Wenatchee, Methow, and Okanogan Rivers. Temporally replicated hatchery-origin summer Chinook were from Wells Hatchery, Eastbank Hatchery - Wenatchee stock, and Eastbank Hatchery - Methow/Okanogan (MEOK) stock. A total of 232 of those individuals were excluded from any analyses because they failed to amplify at nine or more loci. Data for remaining 2,118 individuals were analyzed to assess differences between temporally replicated natural- and hatchery-origin summer Chinook for each location and to compare the differences among the different collection locations. Summer Chinook data from the temporally replicated collection locations were then combined and compared to fall Chinook data from the GAPS v.3.0 dataset.

## Statistical Analyses

The population statistics (Hardy-Weinberg equilibrium and $\mathrm{F}_{\text {IS }}$ ) calculated for each of the 32 temporally replicated collection locations were consistent with neutral expectations (i.e., no associations among alleles). Three collections did have a single locus that did not meet expectations (Wenatchee hatchery-origin 2006, Wells hatchery 2006, and Okanogan hatchery-origin 2009). Based on these results we suggest the collections represented randomly breeding groups and were not comprised of mixtures of individuals from different genetic source populations.

Population differentiation was assessed for each of the temporally replicated collections from within each location (Table 3). This analysis revealed the only significant difference observed within a collection location pertained to the collection from 1993 Okanogan River natural-origin samples. Because of the significant difference of this collection to the other temporal replicates it was not included in further analyses.

Given the absence of genetic differentiation observed among the temporally replicated collections, the 32 collections from the Wenatchee, Methow, and Okanogan River were combined to form three location-specific collections for analysis. Population differentiation metrics were compared among the composite Wenatchee, Methow, and Okanogan collections and eight other location-specific collections ( 11 locations total). Comparing all collections, there were a total of 39 significant genic test comparisons out of a total 496 (Table 4). Thirty-eight of the 39 statistically significant pairwise differences pertained to the Okanogan River and 2006 Wells Hatchery collections (Table 4). Fst results are described further below.

Within-collection genetic metrics were estimated for the 11 location-specific collections of summer Chinook from the upper Columbia River, in addition to eight collections of fall Chinook (Table 1). The population statistics (HardyWeinberg equilibrium and $\mathrm{F}_{\text {Is }}$ ) calculated for these collections of summer and fall

Chinook were also consistent with neutral expectations. The collection from Lyons Ferry Hatchery had one locus that did not meet expectations and the collections from Crab Creek and Marion Drain both had three loci that did not meet expectations.

The hatchery collections in general had a higher percentage of significantly linked loci; however the observed genetic diversity were similar for the natural and hatchery-origin collections. Analysis of allelic richness was based on 11 individuals per collection, the minimum number of individuals across all collections with complete multilocus genotypes. The largest number of linked loci occurred in the Crab Creek, Entiat River, and Okanogan natural-origin collections. Allelic richness was on average lower in the collections of summer Chinook (10.7) collections in comparison to the collections of fall Chinook (11.0).

Pairwise $\mathrm{F}_{\text {ST }}$ (Table 4) estimates revealed low levels of differentiation, where all observed $\mathrm{F}_{\text {ST }}$ values between the collections of summer Chinook were lower than 0.0096 . There were 15 out of 28 comparisons between collections of summer Chinook that were significantly different from zero and occurred primarily from comparisons of the Okanogan River (hatchery and natural-origin) and Wells Hatchery to all other collections. The collection of Eastbank Hatchery - MEOK stock was differentiated from the Wenatchee River natural-origin and Entiat River collections. The collection from the Chelan River had a small sample size of 23 individuals and only differentiated from the Eastbank Hatchery - MEOK stock. $\mathrm{F}_{\text {ST }}$ estimates regarding pairwise comparisons between each of four fall Chinook collection locations (Crab Creek, Lyons Ferry Hatchery, Marion Drain, and Snake River) to all other collections were significantly different from zero (Table 5). Pairwise comparisons for three other fall Chinook collections (Hanford Reach, lower Yakima River, and Umatilla River) to the collections of summer Chinook were significantly different from zero (Table 6). The only fall Chinook collection that was not significantly differentiated from all of the summer Chinook was Priest Rapids.

The relative genetic relationships among the test groups were assessed using the consensus clustering analysis (Figure 1). Statistical support for the dendrogram topology (i.e., tree shape) was low regarding the branching that separated the collections of summer Chinook from the upper Columbia River. The collections of fall Chinook; however were supported with bootstrap support over $76 \%$ with the exception of three collections (lower Yakima River, Crab Creek, and Umatilla River). In other words, 760 of the 1000 bootstrap replicates supported the placement of the node separating summer and fall collections. The collection from the Chelan River had bootstrap support of 68\%; however the sample size for that collections was small $(\mathrm{N}=23)$. Even though the bootstrap support was low among the collections of summer Chinook there was concordance between geography and genetic distance.

Where comparisons were possible between pre- and post-supplementation program collections, the effective number of breeders $\left(N_{b}\right)$ estimated to have comprised those collections were slightly lower for contemporary (2008) collections; however in all cases the 95\% confidence intervals overlapped between historical and contemporary collections, suggesting statistical equivalency. Regarding Wenatchee River collections, the point estimates of $\mathrm{N}_{\mathrm{b}}$ ranged from 134 (08FU) to 190 (93DD), where all collections had overlapping confidence intervals (Table 7). The upper bound of the 1989 brood year for collection 93DD was very large, suggesting the sample size was insufficient for properly inferring the sibship distribution within the collection. Comparing the Okanogan natural collections 93ED and 08GA, the estimated $\mathrm{N}_{\mathrm{b}}$ were 142 (CI 102 - 203) and 127 (CI 92 - 180), respectively. For the Eastbank Hatchery MEOK stock comparisons, the $\mathrm{N}_{\mathrm{b}}$ estimated for the 93DF collection was 171 (CI 129 - 229), as compared to the 166 ( $\mathrm{Cl} 126-226$ ) estimated for collection 08 MO . In all cases, the estimated $\mathrm{N}_{\mathrm{b}}$ can be converted to effective population size $\left(\mathrm{N}_{\mathrm{e}}\right)$ by multiplying the estimate by the mean generation time.

## Discussion

The collections of summer Chinook populations from the upper Columbia River are of interest because census sizes are reduced below historic levels and are the subject of mitigation and supplementation hatchery programs. Concern over the impacts of hatchery supplementation programs on the genetic integrity of natural-origin populations led to our primary objective, which was to evaluate genetic metrics for temporally replicated collections of summer Chinook in the upper Columbia River pre and post hatchery supplementation. A similar analysis by Kassler and Dean (2010) was conducted on spring Chinook in the Tucannon River to evaluate the effects of a supplementation and captive brood program on natural-origin stocks. Additionally, upper Columbia River spring Chinook supplementation programs (Blankenship et al. 2007; Small et al. 2007), spring and fall Chinook populations in the Yakima Basin (Kassler et al. 2008), and a potentially unique population of fall Chinook in Crab Creek (Small et al. 2010) have been evaluated. In the present analysis of summer Chinook populations, collections of pre- and post- supplementation summer Chinook were collected from the Wenatchee River, Methow River, and Okanogan River Basins and analyzed to determine if the genetic profile has changed as a result of the supplementation program. Analysis was then conducted on the collections of summer run to compare the fall run Chinook collections in the upper Columbia River basin.

Allozyme analyses of these three summer run Chinook stocks in the upper Columbia River have identified that each stock was distinct, with a closer relationship detected between the Wenatchee and Methow Rivers (WDF and WDW 1993, Marshall 2002). Wenatchee summer Chinook are thought to be a mixture of native summer Chinook and Chinook from the Grand Coulee Fish Maintenance Project (GCFMP). The goal of the GCFMP project between 1939 and 1943 was to trap migrating Chinook salmon at Rock Island dam ( 75 miles below Grand Coulee) and homogenize the populations, which reduced the
genetic uniqueness of the distinct tributary populations present in the upper Columbia River.

We found allele frequencies for individual temporally replicated hatchery- and natural-origin collection locations of adult summer Chinook were not significantly different from that expected of a single underlying population, except for one collection (1993 Okanogan natural-origin; Table 3). This collection was differentiated to the Okanogan collections in 2006 and 2008; however it was not differentiated from the collection in 1992. The Okanogan collection from 1992 was also not differentiated to any other collection; therefore the difference in the collection from Okanogan 1993 was likely not an indication of genetic change from pre supplementation to post supplementation. The collection was however dropped from further analyses so as to not confuse interpretation of results. The lack of allelic differentiation observed among the temporally replicated collections was interpreted as the genetic metrics from each location in the early 1990's did not differ from the samples collected in 2008. Spanning a few generations, allele frequencies are not expected to change for large populations at genetic equilibrium. In contrast, changes in allele frequencies of small populations may occur due to the stochastic sampling of genes from one generation to the next (i.e., genetic drift).

A second round of analyses was conducted to evaluate the genetic relationships of the summer run collections (temporal collections were combined) with data from the Entiat River, Chelan River, and eight collections of fall Chinook. Assessment of the relationship between the summer run collections in comparison to each other provided very little evidence of genetic differentiation between these collections. While population differentiation did show some significant differences between the Okanogan River and Wells Hatchery collections, all of the pairwise $F_{S T}$ values were below 0.003 . Meaning that a very small proportion of the observed genetic variation could be attributed to restrictions in gene flow (i.e., population structure)

The comparison of the hatchery-origin collections revealed a lack of differentiation between the Eastbank Hatchery - Wenatchee stock, Eastbank Hatchery - MEOK stock, and the Wells Hatchery (with exception of the 2006 collection). The genetic similarity or low level of genetic differentiation among these stocks suggests that there has been an integration of natural- and hatchery-origin summer Chinook in the upper Columbia River or a lack of ancestral genetic difference. The difference of the 2006 Wells Hatchery collection to the other collections is most likely a result of sampling effect because of the lack of differentiation among the stocks in the basin. If the 2006 collection had been mixed from different sources of summer Chinook there would not be a detectable level of differentiation as was seen with the 2006 sample.

The analyses to compare summer and fall Chinook collections provided some understanding on the genetic relationships of Chinook with different run timings in the upper Columbia River basin. Historically, the hatchery programs in the upper Columbia River were separated into groups of the early returning fish (i.e., stream-type) and later returning fish (i.e., ocean-type), but the programs did not sort individuals identified as "summer" or "fall" stocks (Waknitz et al. 1995). Now all Chinook salmon that are migrating above Rock Island Dam descend from a mixture of different stocks from the upper Columbia River basin, but also a mixture between the endemic summer and fall life histories.

Small et al. (2010) conducted an analysis on summer run and fall run Chinook in the upper Columbia River and concluded that Crab Creek Chinook in the upper Columbia River were genetically distinct to all other fall and summer run Chinook stocks that were analyzed. They did note a departure from Hardy Weinberg expectation as a result of a null allele at the microsatellite locus Ogo-4 and a higher linkage disequilibrium value due to the inclusion of family groups in one of their samples. Kassler et al. (2008) found differentiation among spring and fall Chinook populations in the Yakima River.

The tests of pairwise Fst $_{\text {indicated a very low level of genetic differentiation (less }}$ than one percent difference) between collections of summer-run Chinook and fall-run Chinook. The range of pairwise $\mathrm{F}_{\text {St }}$ values for comparisons between the summer run and fall run collections was $0.0016-0.0248$. The larger values from the range were associated to the collections from Crab Creek, Lyons Ferry Hatchery, and Marion Drain. Studies by Kassler et al. (2008) and Small et al. (2010) have documented differences among the populations of these collections to others within the upper Columbia River basin. The low pairwise $\mathrm{F}_{\text {ST }}$ values between Priest Rapids and Hanford Reach collections and the summer run collections were not surprising because summer-run Chinook originating from above Rock Island Dam were believed to have spawned extensively with Hanford Reach and Priest Rapids Hatchery fish during the 1970's and 80's (Chapman 1994). The lack of differentiation among the summer and fall stocks in the Columbia River was also identified by Utter et al. (1995) and the HGMP where they state physical evidence and genetic data suggests that summer and fall Chinook may have become homogenized.

Despite low levels of statistical bootstrap support for dendrogram topology (i.e., tree shape), there was concordance observed between geographic location and the genetic relationships among the summer and fall Chinook populations. The collections from the Okanogan (hatchery and natural-origin) did separate out with collections from Wells Dam Hatchery, Entiat River, and Eastbank Hatchery MEOK stock, and were next to a group of the Methow and Wenatchee collections. The fall Chinook populations are also separated to the summer collections and the position of all but three of these collections (lower Yakima River, Crab Creek, and Umatilla River) were statistically supported. The geographic proximity of the fall collections seemed to follow the observed pattern in this dendrogram. The relationship of the Snake River and Lyons Ferry Hatchery in proximity to the collection from Marion Drain was not surprising while
the relationship between Priest Rapids and Hanford Reach was easily a result of the stocking practices of fall Chinook in the 1970 and 1980's.

A secondary objective of this study was to determine if the effective population size of upper Columbia River summer Chinook populations had changed over time due to supplementation efforts. We observed that the number of effective breeders in the collections from 1993 and 2008 has not changed thus providing reason to believe that the genetic diversity of summer Chinook in the upper Columbia River has not been altered through the supplementation program.

## Acknowledgements

Chelan County PUD, Grant County PUD, and Washington State General Funds provided funding for this project. Cherril Bowman (WDFW - Molecular Genetics Laboratory) processed samples in the laboratory. Maureen (Mo) Small provided data for some collections and discussion of the analyses. USFWS provided data from the Entiat River.

Table 1. Samples of adult hatchery- and natural-origin summer and fall Chinook that were analyzed from the upper Columbia River. Total number of individuals that were analyzed / individuals with data for 9 or more loci that were included in the analysis. Collection statistics (allelic richness, linkage disequilibrium (before and after Bonferroni correction), $\mathrm{F}_{\text {IS }}$, heterozygosity $\left(H_{O}\right.$ and $\left.H_{E}\right)$ ) and $p$-values for deviations from Hardy-Weinberg equilibrium (HWE). P-values were defined as significant after implementation of Bonferroni correction for multiple tests (Rice 1989).

Table 3. Tests of population differentiation for temporal collections of summer Chinook from natural and hatchery-origin populations in the upper Columbia River. P-values that are highlighted grey are significantly different after Bonferroni correction (Rice 1989). Adjusted alpha p -value was 0.0001 . The H and W in the collection identifier is for wild or hatchery-origin and the two digit number identifes the year samples were collected.

## APPENDIX K

Summer Chinook Spawning Ground Surveys in the Methow and Okanogan Basins, 2010.

January 11, 2011

## To: HCP Hatchery Committee

From: Denny Snyder and Mark Miller
Re: 2010 Spawning Ground Surveys in the Okanogan and Methow Basins
The purpose of this memo is to provide information on the hatchery-supplemented natural spawning population of summer Chinook in the Methow and Okanogan basins. This work is part of a larger effort focused on monitoring and evaluating Chelan PUD's hatchery supplementation program. The tasks and objectives associated with implementing Chelan PUD's hatchery M\&E plan for 2010 are outlined in several documents (Murdoch and Peven 2005; Peven 2006; Hays et al. 2006). Figures and tables are presented at the end of this memo.

## METHODS

Spawning ground surveys were conducted by foot, raft, and aircraft beginning the last week of September and ending mid-November. During aerial surveys an observer recorded the location and number of redds on topographic maps. We did not use aerial surveys on the Methow River because past work has demonstrated that ground counts were more accurate than aerial surveys (Miller and Hillman 1997). Because of the depth of redds, aerial surveys were the only census method used for the Columbia River downstream from Wells (tailrace area only) and Chief Joseph dams. Ground surveys were used to provide more accurate counts and a complete census of Chinook redds within their spawning distribution. Observers floated through sampling reaches and recorded the location and numbers of redds each week. Observers recorded the date, water temperature, river mile, and constructed a drawing of the area where redds were located. A different symbol was used each week to record the number of new and incomplete redds.

To maintain consistency, at least one observer surveyed the same stream reach on successive dates. In areas where numerous summer Chinook spawn, we constructed detailed maps of the river and used the cell-area method (Hamilton and Bergersen 1984) to identify the number of redds within each cell. Cells were bound by noticeable landmarks along the banks (e.g., bridges or trees) or at stream habitat boundaries (e.g., transitions between pools and riffles). The number of redds were then recorded in the
corresponding grid on the map. When possible, observers estimated the number of redds in a large disturbed area by counting females that defended their redds. We assumed that the area or territory defended by a female was one redd.

During redd surveys, we sampled carcasses of summer Chinook to describe the spawning population. Biological data included collection of scale samples for age analysis, length measurements ( POH and FKL), gender, egg voidance, and a check for tags or marks. These data will be used to assess length-at-age, size-at-age, egg voidance, origin (hatchery or naturally produced), and stray rates. No DNA samples were collected on summer Chinook this year. Information on summer Chinook spawning in the Chelan River was collected by Chelan PUD and is presented in the results.

## RESULTS

## Methow

There were 887 summer Chinook redds counted within seven reaches of the Methow River (Table 1). This was the fifth highest redd count observed in the last 19 years for the Methow River (Table 3). Spawning began the last week of September and peaked the second week of October and continued into the second week of November (Table 1; Figure 1). Stream temperatures in the Methow River, when spawning began, varied from $6.5-12.0{ }^{\circ} \mathrm{C}$. Peak spawning occurred in reaches (M2-M6) of the Methow River during the second week of October. The lowest reach (M1) had spawning throughout October with a slight peak the second week. Most redds (87\%) were located in reaches (M1-M3) downstream from the town of Twisp and in reach (M5) between Methow Valley Irrigation Diversion (MVID) and Winthrop Bridge (Table 1). Few summer Chinook spawned (1\%) upstream from the Winthrop Bridge in reaches M6 and M7. Estimated escapement based on redd counts and the sex-ratio observed at Wells Dam during broodstock collection suggests that 2,492 summer Chinook ( 887 redds x 2.81 fish/redd) escaped to the Methow River.

There were 577 summer Chinook salmon carcasses sampled within the different reaches of the Methow River (Table 2). Twenty-three percent of the fish returning to the Methow River were sampled based on the estimated escapement of 2,492 summer Chinook. Females made up $46 \%$ and males $54 \%$ of the carcasses examined. Mean percent egg voidance assessed from 266 female carcasses was $98 \%$. Two females ( $1 \%$ ) died before spawning (i.e., they retained all their eggs). Ad-clipped hatchery fish made up $46 \%$ and naturally produced fish were $54 \%$ of the sample collected (Table 2). The distribution of ad-clipped hatchery and naturally produced fish showed that more than half $(92 \%)$ of the ad-clipped hatchery fish were located in the lower three reaches while naturally produced fish were more evenly distributed (Figure 2).

## Okanogan

There were 1,011 summer Chinook redds counted within six reaches of the Okanogan River (Table 1). This was the tenth highest redd count observed in the last 21 years for
the Okanogan River (Table 3). Peak aerial redd counts ( 688 redds) were about 68 percent of redds counted from the ground. Spawning began the last week of September and peaked two weeks later in mid-October (Figure 1). Spawning was initiated in the Okanogan River when the stream temperature varied from $8.5-16^{\circ} \mathrm{C}$. Spawning activity ended after the first week of November (Table 1; Figure 1). Peak spawning in the Okanogan River occurred during the second week of October for reaches O4 through O6 with the lower reaches peaking the following two week. Most redds (78\%) were located in the upper reaches (O5 and O6) between Zosel Dam and the town of Riverside (Table 1). Estimated escapement ( 1,011 redds $x 2.81$ fish/redd) to the Okanogan River was 2,841 summer Chinook.

There were 678 summer Chinook salmon carcasses sampled within 6 reaches of the Okanogan River (Table 2). Twenty-four percent of the fish returning to the Okanogan River were sampled based on the estimated escapement of 2,841 summer Chinook. Females made up $44 \%$ and males $56 \%$ of the carcasses examined. Mean percent egg voidance from 297 female carcasses was $99 \%$. No females died before they spawned. Ad-clipped hatchery fish made up $41 \%$ and naturally produced fish $59 \%$ of the sample collected (Table 2). Most naturally produced (52\%) and ad-clipped hatchery fish (35\%) were collected in the upper reaches (O5 and O6) of the Okanogan River closely following the distribution of redds (Figure 2).

## Similkameen

There were 1,107 summer Chinook redds counted within the two reaches of the Similkameen River (Table 1). This was the eight highest redd count recorded in the Similkameen River in the last 22 years (Table 3). The peak aerial count ( 642 redds) was about $58 \%$ of redds counted on the ground. Spawning began the last week of September and peaked the second week in October (Figure 5). Spawning was initiated in the Similkameen River when the temperature varied from $13.5-15^{\circ} \mathrm{C}$. Spawning activity ended by the first week of November (Table 1). Most (81\%) spawning occurred in the lower reach from the Oroville Bridge, downstream to the Driscoll channel on the Similkameen River. Estimated escapement ( 1,107 redds x 2.81 fish/redd) to the Similkameen River was 3,111 summer Chinook.

There were 775 summer Chinook salmon carcasses sampled within the two reaches of the Similkameen River (Table 2). Twenty-five percent of the fish returning to the Similkameen River were sampled based on the estimated escapement of 3,111 summer Chinook. Females made up $65 \%$ and males $35 \%$ of the carcasses examined. Mean percent egg voidance from 505 female carcasses was $99 \%$. One female ( $1 \%$ ) died before it spawned. Ad-clipped hatchery fish made up $47 \%$ and naturally produced fish $53 \%$ of the sample collected (Table 2).

## Chelan River

Chelan County PUD biologists counted 398 redds in the Chelan River area. Spawning activity in the Chelan River began mid-October and peaked two weeks later (Table 1).

Spawning ended the third week of November. The majority (86\%) of spawning occurred in the Chelan tailrace and in the habitat channel (Table 1). Estimated escapement (398 redds x 2.81 fish/redd) to the Chelan River was 1,118 summer Chinook.

There were 106 summer Chinook carcasses sampled in the Chelan River area (Table 2). Nine percent of the summer Chinook returning to the Chelan River were sampled based on the estimated escapement of 1,118 fish. Sampling focused on collection of CWT snouts, especially during the earlier surveys, thus the proportion of unmarked (ad present) fish in the data set is biased low. Females made up $85 \%$ and males $15 \%$ of the carcasses examined. The sample rate was likely higher for females and low for the males. Mean percent egg voidance from 76 female carcasses was $93 \%$. Five females (7\%) died before spawning. Ad-clipped hatchery fish made up $56.6 \%$ and naturally produced fish $43.4 \%$ of the sample collected.

## Columbia River

Aerial surveys were used to count the number of redds in the Columbia River. The surveys were conducted downstream from Wells Dam and in Wells pool. The redd counts likely underestimate the true number of redds because aerial surveys only count visible redds and it is likely that spawning may occur in deep water. Aerial surveys in 2010 were also hampered by poor visibility or weather conditions. There were 48 Chinook redds counted in the Columbia River (Table 1). Twenty two redds were located downstream from Wells Dam in an area that has been documented before (Giorgi 1992). An aerial survey in Wells pool located an estimated 26 redds downstream from Chief Joseph Dam between the bridge and Foster Creek near the left bank. Observations in this area were difficult because distinct outlines of some redds were not readily apparent and most of the spawning occurred in a large single cluster. During the aerial survey, we observed at least five carcasses downstream from Chief Joseph dam.

A radiotelemetry study on movement and migration patterns of summer Chinook in the Wells Pool suggests that spawning occurs in the Columbia River (Ashbrook et al. 2008). Many of the radio-tagged Chinook resided near the tailrace of Chief Joseph Dam along the right and left banks near the location where the redds were observed. Next year we plan to investigate this area to confirm these observations by retrieving carcasses and to see if snorkeling is a viable method for observing redds at this locations. Estimated escapement ( 48 redds x 2.81 fish/redd= 135 fish) based on aerial surveys suggests that at least 135 Chinook spawned in the Columbia River. No carcasses were examined for these two spawning areas.

Peven, Chuck. 2005. Chelan County PUD Hatchery Implementation Plan 2006. Prepared for Chelan PUD Habitat Conservation Plan's Hatchery Committee, Chelan PUD, Wenatchee, WA.

Figure 1. Number of new redds counted each week from mid-September to mid-November. The figure displays the beginning, peak, and end of spawning for summer Chinook in the Methow, Okanogan, and Similkameen rivers in 2010 compared to a 19 -year average (1991-2009).

Figure 2. Percent distribution of ad-clipped hatchery and naturally produced fish plotted against the percent distribution of redds observed in reaches of the Methow, Okanogan, and Similkameen rivers, 2010.

Table 1. Number of summer Chinook redds observed each week within the Methow, Okanogan, Similkameen, Chelan, and Columbia rivers, 2010. Dashes indicate no survey occurred and poor visibility is indicated as PV during aerial surveys on the Columbia River.

${ }^{1}$ Chelan PUD examined 106 carcasses. Sampling was focused on collection of CWT snouts, especially during the earlier surveys, thus the proportion of naturally produced Chinook (ad present) in the data set is biased low.
${ }^{2}$ Six fish of the 37 naturally produced Chinook examined in the habitat channel were not assigned a gender.

Table 3. Historical aerial and ground redd counts of summer Chinook in the Methow, Okanogan, and Similkameen rivers, 1957-2010.

[^0]:    ${ }^{1}$ In this report we use two methods of describing age. One is termed the "European Method." This method has two digits, separated by a period. The first digit represents the number of winters the fish spent in freshwater before migrating to the sea. The second digit indicates the number of winters the fish spent in the ocean. For example, a fish designated as 1.2 spent one winter in freshwater and two in the ocean. A fish designated as 0.3 migrated to the ocean in its first year and spent three winters in the ocean. The other method describes the total age of the fish (egg-to-spawning adult, i.e., gravel-to-gravel), so fish demarcated as 0.3 or 1.2 are considered 4 -year-olds, from the same brood.

[^1]:    ${ }^{2}$ It is very unlikely that observer efficiency is $100 \%$, especially within the White River.
    3 Adult sockeye that were tagged at Bonneville Dam and detected at Tumwater Dam were included in the markrecapture analyses.

[^2]:    ${ }^{4}$ A steelhead/rainbow trout larger than 200 mm (8 in) was considered a resident trout.

[^3]:    ${ }^{1}$ Unnamed tributary that drains the eastside of Chiwawa Ridge. Its confluence with the Chiwawa River is about 1 mile ( 1.6 km ) downstream from the mouth of Phelps Creek.

[^4]:    ${ }^{2}$ The study period 1992-2010 includes only 18 years of sampling because there was no sampling in 2000.
    ${ }^{3}$ The habitat use index was calculated as follows: Multiple channel use $=\left(\operatorname{parr}_{m c} / \operatorname{parr}_{t}\right) /\left(\operatorname{area}_{m c} /\right.$ area $\left._{t}\right)$, where parr $m c$ $=$ the number of parr counted in multiple channel habitat, $\operatorname{parr}_{t}=$ the total number of parr counted within all habitat types, area $_{m c}=$ the area of multiple channel habitat within the sampling frame, and area ${ }_{t}=$ the total area of the sampling frame. A multiple channel use index value of 1 would indicate that parr were uniformly distributed among habitat types and exhibited no preference for multiple habitat types. Values of the use index greater than 1 indicate

[^5]:    ${ }^{4}$ The $\gamma$ parameter in the Gamma model was greater than 0 , which means that this model is nearly identical to the Ricker model. The reason it did not rank higher is because it contains an extra parameter, which means that it has less bias and greater variance than the Ricker model.

[^6]:    ${ }^{5}$ Because there are no estimates for probability of detecting bull trout with daytime underwater observation methods in the Chiwawa Basin, we could not adjust bull trout numbers based on detectability. Therefore, the numbers reported in this report likely underestimate the "true" number of bull trout in the survey area.

[^7]:    ${ }^{1}$ Includes the lower 0.2 miles of Minnow Creek

[^8]:    ${ }^{1}$ Includes lower 0.2 miles of Minnow Creek.

[^9]:    ${ }^{1}$ Includes lower 0.2 miles of Minnow Creek.

[^10]:    ${ }^{1}$ Includes lower 0.2 miles of Minnow Creek.

[^11]:    ${ }^{1}$ Includes lower 0.2 miles of Minnow Creek.

[^12]:    ${ }^{1}$ Includes lower 0.2 miles of Minnow Creek.

[^13]:    ${ }^{1}$ Includes lower 0.2 miles of Minnow Creek.

[^14]:    * Ages not confirmed by scales.

[^15]:    ${ }^{a}$ No redd counts
    ${ }^{\mathrm{b}}$ Partial basin redd counts
    ${ }^{\text {c }}$ Incomplete brood year

[^16]:    1/- Defined as "above Wells Dam" because hatchery origin, adipose-clipped steelhead release into the Methow River from the Wells FH and Winthrop NFH have the same marks and are indistinguishable for one another.

[^17]:    ${ }^{1}$ The majority of Chinook that ascend the mid-Columbia River as adults after July spawn between October and November in the mainstem of the Columbia, Wenatchee, Methow, Similkameen and Okanogan rivers. These fish have been called "summer" and "fall" Chinook based on their migration timing past the dams. Their life histories are identical (Mullan 1987), and should be termed "late-run" to separate them from earlier running "spring" Chinook that have a different life history. For consistency with previous year's reports, only the earlier segment of the late-run (those that ascend Rock Island Dam between June 24 and September 1; "summers") will be focused on in this report.

[^18]:    ${ }^{1}$ Samples taken from scale cards provided by Jeff Fryer (CRITFC)
