# The Chief Joseph Hatchery Program Summer/Fall Chinook 

2019 Annual Report

BPA Project Number 2003-023-00
CCT Project No. 312419 and 312219
This report covers work performed under contracts \#73548, Rel 56 (M\&E) and \#73548, Rel 57 (O\&M) for the performance period May 1, 2019 to April 30, 2020.

Prepared by:
Andrea Pearl ${ }^{1}$, Matthew B. Laramie ${ }^{2}$, Casey Baldwin ${ }^{1}$, Kirsten Brudevold ${ }^{1}$, Brian Dietz ${ }^{1}$, Matt McDaniel ${ }^{1}$
${ }^{1}$ Colville Confederated Tribes
Fish and Wildlife Program, Anadromous Division
P.O. Box 150

Nespelem, WA 99155
${ }^{2}$ U.S. Geological Survey - Forest and Rangeland Ecosystem Science Center 230 N. Collins Road, Boise, Idaho, 83702

Prepared for:
Bonneville Power Administration, and
Chelan, Douglas \& Grant County Public Utility Districts
February 1, 2023

This report was funded by the Bonneville Power Administration (BPA), the U.S. Department of Energy, as part of BPA's program to protect, mitigate, and enhance fish and wildlife affected by the development and operation of hydroelectric facilities on the Columbia River and its tributaries. The views in this report are the authors, except for the U.S. Geological Survey author, and do not necessarily represent the views of BPA, other funding entities, or the Colville Confederated Tribes (CCT).

Cost shares for specific portions of this project were provided by the U.S. Geological Survey and the Washington State Recreation and Conservation Office. General cost shares were also provided by the Chelan, Douglas, and Grant County Public Utility Districts as part of their mitigation obligations under their respective hydroelectric project settlement agreements.

This report includes both hatchery production/operations and the corresponding monitoring activities completed through April of 2020. It is structured to meet the RM\&E technical report formatting requirements for BPA, and therefore the hatchery production portion is included in Appendix A.

Reports, program descriptions, annual review materials and background information, news and contact information can be found on our website at: https://www.cct-fnw.com/reports/.

All photos are credited to Confederated Tribes of the Colville Reservation Fish and Wildlife Department - Chief Joseph Hatchery Program unless otherwise noted.

## Acknowledgments

The list of people responsible for planning, designing, building, funding, and implementing the Chief Joseph Hatchery ( CJH ) is too long to mention here. None of the authors of this report were involved in the initial efforts to convince the Federal government to fund this endeavor, but we are grateful for the efforts. As are the Colville Tribal fishermen and other fishermen from Alaska, British Columbia, the Washington Coast, and all through the Columbia River who will benefit from the fish production for many generations to come. We wish to acknowledge Joe Peone, CCT Fish \& Wildlife Program Director, Kirk Truscott, CCT Anadromous Division Manager, the Colville Business Council and the Natural Resource Committee for their policy direction and program guidance. This hatchery program would not exist today if not for the vision and dedicated efforts of a variety of current and former employees of CCT and BPA, particularly the former CCT Fish and Wildlife Program Manager, Randall Friedlander and the former CCT Anadromous Division Manager, Jerry Marco. Additionally, expert contributions, counsel, and examples came from a variety of staff from management agencies (WDFW, USFWS), groups (Mid-C HCP hatchery committees), and contractors to the Colville Tribes. Some of the tables, formatting, and table header text were copied from the CPUD/GPUD 2013 annual report to provide continuity with reporting for other populations in the Upper Columbia River and past reporting in the Okanogan River.

We want to thank our skilled and dedicated CJHP staff who cared for the fish, collected the data, maintained the equipment, and generally did whatever was necessary for the project to be successful. We appreciate their willingness to work long hours under adverse conditions to get the job done.

Administrative support for CCT was provided by Kary Nichols, Jeannette Finley, Therilyn Williams, Fauna Ferguson, Roma Tynan, Billy Gunn, Cindy McCartney, Shelly Davis, Erica DeLeon, L.J. Stensgar, and others within the Tribal government. We greatly appreciate the administrative support of Maureen Kavanagh, the BPA contract officer technical representative for this project. These individuals provide collaboration on accounting and procurement and the considerable administrative transactions necessary to support a program of this scope.

We would also like to extend our appreciation to the many private landowners, Colville Tribal members, State and Federal agencies, the Okanagan Nation Alliance, and the Penticton and Osoyoos Indian Bands in Canada, who have provided land access and other forms of assistance enabling us to collect biological and other data within the Okanogan and Columbia Basins.

Any use of trade, product, or firm names is for descriptive purposes only and does not imply endorsement by the U.S. Government or the Confederated Tribes of the Colville Reservation

Table C 3. Salt age structure (percent of recovered carcasses) for sex-origin classes. ..... C-21
Table C 4. Estimated number and percent of hatchery-origin Okanogan/Similkameen summer Chinook captured in different fisheries, brood years 1989-2011 ..... C-25

## Executive Summary

The Colville Confederated Tribes (CCT) Chief Joseph Hatchery (CJH) is the fourth hatchery obligated under the Grand Coulee Dam/Dry Falls project, originating in the 1940s. Leavenworth, Entiat, and Winthrop National Fish Hatcheries were built and operated as mitigation for salmon blockage at Grand Coulee Dam, but the fourth hatchery was not built, and the obligation was nearly forgotten. After the Colville Tribes successfully collaborated with the United States to resurrect the project, planning of the hatchery began in 2001 and construction was completed in 2013. The monitoring program began in 2012 and adult Chinook Salmon were brought on station for the first time in June 2013. Bonneville Power Administration (BPA) is the primary funding source for CJH , and the Mid-Columbia PUDs (Douglas, Grant, and Chelan County) have entered into cost-share agreements with the tribes and BPA in order to meet some of their mitigation obligations.

The CJH production level was set at 100\% in 2019 during the seventh year of operation for the Summer/Fall Chinook program. In July and August the CCT used a purse seine vessel to collect 1,223 summer/fall Chinook for broodstock for both the integrated and segregated programs (including Similkameen). Additionally, 10 summer/fall Chinook were collected at the Okanogan adult weir in August and September. The summer/fall Chinook program collected enough brood to meet full production level. The cumulative pre spawn holding survival, for all Summer/Fall brood collected, was 89.9\% for hatchery-origin broodstock (HOB) and 95.8\% for natural-origin broodstock (NOB). The survival standard ( $90 \%$ ) was met by both the hatcheryorigin and natural-origin brood. Total green egg take for the season was 2,530,220 (93\% of full program). Egg survival from green egg to eyed egg averaged $82.9 \%$ for NOB and $87.2 \%$ for HOB, both under the survival standard (90\%) for this life stage. Cumulative egg survival from green egg to eyed egg was $82.9 \%$ for NOB and $87.2 \%$ for HOB, which is under the survival standard ( $90 \%$ ) for this life stage. After in-hatchery mortalities from pre-spawn holding through ponding there were 1,354,996 fish on hand at the end of April for the yearling releases in 2021 (93\% of the yearling program) and 565,777 fish on hand for the sub-yearling releases in May 2020 (81\% of full program).

2019 was the fifth year for Summer/Fall Chinook hatchery yearlings released from the CJH, Similkameen and Omak acclimation ponds. In April, 280,055 integrated yearling summer/fall Chinook were released from the Omak acclimation pond and 240,812 were released by Washington Department of Fish \& Wildlife (WDFW) from the Similkameen Pond; combined these programs were at $87 \%$ of the full program goal of 800,000 integrated yearlings. There were no integrated or segregated sub-yearlings from brood year (BY) 2018 released in May 2019. However, there were 399,299 yearling Chinook released directly from Chief Joseph Hatchery (80\% of full program).

After release, the yearling programs from CJH and Omak Pond had similar survival when compared to previous years and other programs. Although CJH survival was about 7\% below the -five-year mean, the travel time was considerably longer (11-12 days to Rocky Reach and McNary dams). In contrast, the travel time for fish released from Omak Pond was only 2-5 days slower than the five-year mean to Rocky Reach and McNary dams and the resulting survival was $0-4 \%$ higher than the five-year mean. The majority ( $>90 \%$ ) of PIT tagged hatchery smolts released from Omak Pond migrated to the lower Okanogan River within three weeks of release. Although overall outmigration was slower than in previous years, this assessment suggests that the program was successful at releasing actively migrating smolts.

The CJH monitoring project collected field data to determine Chinook population status, trend, and hatchery effectiveness centered on six major activities; 1) rotary screw traps (juvenile outmigration, natural-origin smolt PIT tagging) 2) beach seine (natural-origin smolt PIT tagging, smolt to adult return) 3) lower Okanogan adult fish pilot weir (adult escapement, proportion of hatchery-origin spawners [pHOS], broodstock) 4) spawning ground surveys (redd and carcass surveys)(viable salmonid population [VSP] parameters) 5) eDNA collection (VSP parameter-distribution/spatial structure) and 6) coded wire tag lab (extraction and reading).

Rotary screw trap operations began on April 1 and continued through June 19, capturing 3,880 natural-origin Chinook and 290 hatchery-origin Chinook. After conducting 2 markrecapture events, the efficiency of the trapping configuration was calculated to be approximately $0.65 \%$. Because of the inability to collect sufficient data to confidently estimate juvenile outmigration, abundance estimates were not produced for the 2019 outmigration. 934 steelhead ( 0. mykiss) were also captured in the rotary screw trap including 32 natural-origin (adipose fin present and no CWT) and 902 hatchery-origin (adipose fin clipped and/or CWT present). Other species commonly caught in the rotary screw traps included Sockeye (O. nerka) (961), Yellow Perch (P. flavescens) (59), Northern Pikeminnow (P. oregonensis) (279), Bridgelip Sucker (C. columbianus) (38), and Mountain Whitefish (Prosopium williamsoni) (519).

Beach seining captured 26,757 juvenile Chinook and 26,439 (98\%) were PIT tagged and released. Pre- and post-tag mortality was $2.8 \%$ and $2.5 \%$ respectively. In 2019, wild summer Chinook tagged at the mouth of the Okanogan had a minimum apparent survival of $36 \%$ (2\% SE) to Rocky Reach Juvenile Bypass (RRJ) and 53\% ( $16 \%$ SE) to McNary (MCN).

The lower Okanogan Adult Fish Weir was deployed on July 15th when discharge was 1,540 cfs. The thermal barrier was present in the lower Okanogan after installation until August 22nd when the mean Okanogan River temperature began dropping below $22.5^{\circ} \mathrm{C}$, allowing Chinook to migrate up the Okanogan. After reviewing the number of adult Chinook pit tagged at Bonneville and their detections at the Wells Adult Ladder and the Lower Okanogan Pit Array, we suspect that about $26 \%$ of fish passage occurred before the weir trap was operational in late August. In August pickets were up on the weir panels due to a high density of algae in the river. The algae created a dense blanket across the weir panels, and it became too difficult for field
staff to maintain the weir without creating a head differential across the panels that was within the project's operating criteria.

Trapping occurred on 5 total days with the majority (87\%) being caught from September 9-11. One hundred and fort-three adult Chinook were trapped in 2019. Ten natural-origin and two hatchery-origin Chinook were transported to the hatchery and held as broodstock for the integrated program. Adult brood were transported from the weir trap to the hatchery brood truck by foot using a rubber boot. There were no immediate mortalities of these fish within the first week after transport to the hatchery. All other natural-origin fish were released upstream of the weir unharmed. All of the hatchery-origin fish encountered in the weir trap were released upstream. Only $2.3 \%$ of the Chinook spawning escapement was detected in the trap. All Chinook and Sockeye mortality encountered at the weir were categorized as impinged on the upstream side, indicating that they most likely died upstream and floated down onto the weir. There were only 7 Chinook carcasses collected from July-September, however, this is likely an underestimate since weir panels were open for most of the season. There was no immediate increase in mortality within that two-week period. The head differential, river velocity, and trap capacity were within the NOAA standard operating criteria. Water quality information, including dissolved oxygen, turbidity, and total dissolved solids were collected to assess potential impacts to increased fish mortality. Weir trapping operations ceased on September 11.

Spawning ground surveys estimated 2,371 summer/fall Chinook redds and 467 carcasses were recovered (226 natural-origin and 241 hatchery-origin). Adult summer/fall Chinook spawning escapement in 2019 was estimated to be 5,453 , with 2,604 natural-origin spawners and 2,849 hatchery origin spawners. In 2019, the effective $\mathrm{pHOS}(0.47)$ and the proportion of natural influence (PNI) (0.57) did not meet the program objectives ( $<0.3 \mathrm{pHOS}$, $>0.67$ PNI). The failure to meet PNI in 2019 was due to a conscious management decision to decrease the pNOB (0.63) in a year with relatively low natural-origin returns. This decision was made to allow more natural-origin fish to escape for spawning in the river, knowing that the 5year average PNI would still remain above the long-term goal. The five-year average for pHOS (0.29) and PNI ( 0.78 ) met the long-term goal ( $<0.30 \mathrm{pHOS} ;>0.67 \mathrm{PNI}$ ). Selective harvest activities by CCT and WDFW contributed to the reduced pHOS and increased PNI in 2019. CCT removed 1,445 hatchery fish, including 41 jacks, during surplus events at the CJH ladder and trap, and tribal members removed another 1,314, including 51 jacks, at the Chief Joseph Dam tailrace fishery. The Harvest program's purse seine removed 101 hatchery fish, including 95 jacks. 15 natural-origin fish, including 1 jack, were released during surplus at the Chief Joseph Hatchery ladder. The purse seine released 182 natural-origin jacks during their efforts. All natural-origin adults encountered with the purse seine were collected for broodstock for the program. The Okanogan temporary weir encountered 143 fish in 2019, in which no hatchery fish were removed and 111 natural-origin fish, including 37 jacks, and 22 hatchery-origin fish were released back to the river. Within the WDFW state fishery, 1,931 hatchery Chinook,
including 98 jacks, were harvested and 967 natural-origin Chinook, including 55 jacks were released back to the river.

The management strategy for the CJH integrated hatchery program in the Okanogan River appears to be having some of the intended effects on the spawning grounds. The intent of adding the Omak Acclimation Pond was to reduce spawning density and pHOS in the high density reaches of the upper Okanogan (06) and lower Similkameen (S1) and to increase spawning in the under-utilized lower and middle reaches of the Okanogan (02-05).

Indeed, spawner distributions have changed during the CJH-era (2016-2019) compared to years prior. We find an increased proportion of redds in reaches 02 thru 06, and reduced proportions in reaches S1 and S2 for years 2016-2019 compared to years 2006-2015. Additionally, carcass recovery data show shifts in the composition of spawners, with increased pHOS in the lower basin (Reach 02) and reduced pHOS upstream. These changes in composition and distribution of spawners across the basin are likely the results of hatchery acclimation strategies, specifically with hatchery fish relating to their Omak Pond acclimation site in the lower basin and should help with the effectiveness of natural-origin spawners in the prime spawning habitat in the upper basin (Reach 06 and S1).

The CJH coded wire tag lab was in its fourth year of operation in 2019. Coded wire tags were extracted and read from Chinook snout recoveries from broodstock, ladder surplus, purse seine harvest, and creel and spawning ground surveys. The development of in-house CWT reading continues to be a huge success, providing age- and origin data within 2-3 months of the spawning ground surveys utilizing Colville tribal staff, rather than outsourcing to another lab. The majority of the summer Chinook adult returns to the CJH ladder were CJH Segregated (53\%) followed by Wells Hatchery (30\%), Chelan Falls (8\%), Dryden (4\%), Okanogan integrated (4\%), and three other programs made up the remaining $1 \%$.

The majority (66\%) of hatchery-origin spawners recovered on the spawning grounds in 2019 were from Similkameen (44\%) and Okanogan (24\%). Chief Joseph Hatchery segregated Chinook comprised $36 \%$ of the HOS on the Okanogan spawning grounds. This level of segregated hatchery fish on the spawning grounds did not meet the program objective ( $<5 \%$ ) and future management efforts should focus on reducing the stray rate of segregated hatchery fish to the Okanogan spawning grounds. However, removal of segregated hatchery fish in low abundance years, such as 2019, is a challenge because integrated hatchery fish are needed to meet escapement goals. Overall, the majority of fish acclimated at Similkameen Pond ended up spawning throughout the upper reaches of the Okanogan (reaches 05 \& 06) and Similkameen Rivers (51\%). Reach S1, the location of the Similkameen acclimation site in the Similkameen River accounted for almost half of the estimated spawning by Similkameen Pond fish (48\%). The most recent brood year that could be fully assessed (through age 5) for stray rate of Okanogan/Similkameen fish to spawning areas outside the Okanogan was 2014. The 2014 brood year had a stray of $0.9 \%$ to non-target basins and $1.0 \%$ to non-target hatcheries, which
was similar to the long term and recent five-year average ( $1.0 \%$ for non-target basins and $0.2 \%$ to non-target hatcheries).

An Annual Program Review (APR) was held in April 2020 to share hatchery production and monitoring data, review the salmon forecast for the upcoming year, and develop action plans for the hatchery, selective harvest, and monitoring projects. Based on a lower-thanaverage pre-season forecast of 38,300 Upper Columbia summer/fall Chinook, the plan for 2020 is to still operate the hatchery at full program levels of 2 million summer/fall Chinook with a reduced pNOB. pNOB was set at $50 \%$ natural-origin broodstock for the integrated program and CCT would not plan to harvest any of their allocation with the selective harvest program, including removals at the purse seine, the weir, and at the hatchery ladder.

## INTRODUCTION

Salmon (Oncorhynchus spp.) and steelhead (O. mykiss) faced many anthropogenic challenges ever since European settlement of the Pacific Northwest. Harvest, hydropower development, and habitat alteration/disconnection have all had a role in reducing productivity or eliminating entire stocks of salmon and steelhead (MacDonald 1894; UCSRB 2007). These losses and reductions in salmon had a profound impact on Native American tribes, including the Confederated Tribes of the Colville Reservation. Hatcheries have been used as a replacement or to supplement the wild production of salmon and steelhead throughout the Pacific Northwest. However, hatcheries and hatchery practices can pose a risk to wild populations (Busack and Currens 1995; Ford 2002; McClure et al. 2008). As more studies lead to a better understanding of hatchery effects and effectiveness, hatchery reform principles were developed (Mobrand et al. 2005; Paquet et al. 2011). The CJHP is one of the first of its kind to be structured using many of the recommendations emanating from Congress's Hatchery Reform Project, the Hatchery Science Review Group (HSRG) and multiple independent science reviews. Principally, the success of the program is not based on the ability to meet the same fixed smolt output or the same escapement goal each year. Instead, the program is managed for variable smolt production and natural escapement. Success is based on meeting targets for abundance and composition of natural escapement and hatchery broodstock (HSRG 2009). Chief Joseph Hatchery Program (CJHP) managers and scientists are accountable for accomplishments and/or failures, and therefore, have well-defined response alternatives that guide annual program decisions. For these reasons, the program is operated in a manner where hundreds of variables are monitored, and activities are routinely and transparently evaluated. Functionally, this means that directed research, monitoring, and evaluation (RM\&E) are used to determine status and trends and population dynamics and are conducted to assess the program's progress in meeting specified biological targets, measure hatchery performance, and in reviewing the key assumptions used to define future actions for the entire CJHP.

The actions being implemented by the Colville Tribes, in coordination with regional management partners, represent an extraordinary effort to recover Okanogan and Columbia River natural-origin Chinook Salmon populations. In particular, the Tribes have embraced hatchery program elements that seek to find a balance between artificial and natural production and address the goals of increased harvest and conservation.

Two hatchery genetic management plans (HGMPs) were initially developed for the CJH during the Northwest Power and Conservation Council (NPCC) three-step planning process one for summer/fall Chinook (CCT 2008a) and one for spring Chinook (CCT 2008b). Each of the two plans included an integrated and a segregated component. Integrated hatchery fish have a high proportion of natural origin parents, are released into the Okanogan River system and a proportion of these fish are expected to spawn in the natural environment. Segregated fish have primarily hatchery parents, are to be released from CJH directly into the Columbia River and adult returns are targeted exclusively for harvest.

In 2010 the CCT requested that the National Marine Fisheries Service (NMFS) designate a non-essential experimental population of spring Chinook in the Okanogan utilizing section 10 (j) of the Endangered Species Act (ESA). In order to obtain a permit to transfer ESA listed fish from the Methow River to the Okanogan River, a new HGMP was developed (CCT 2013). Biological Opinions (BiOps) and permits have been issued by NMFS for the 2008 HGMPs, and CCT acquired a BiOp and permit for the 2013 spring Chinook in 2014. The program will be guided by all three HGMPs.

At full program the facility will rear up to 2 million summer/fall Chinook and 900,000 spring Chinook. Up to 1.1 million summer/fall Chinook will be released in the Okanogan and Similkameen Rivers as an integrated program and 900,000 will be released from CJH as a segregated program. Up to 700,000 segregated spring Chinook will be released from CJH and up to 200,000 Met Comp spring Chinook from the Winthrop National Fish Hatchery (WNFH) will be used to reintroduce spring Chinook to the Okanogan under section 10(j) of the ESA. In 2017, the summer/fall and spring Chinook program's production level was set at full production capacity.

The CJHP will increase harvest opportunity for all anglers throughout the Columbia River and Pacific Ocean. Additionally, the Colville Tribes and other salmon co-managers have worked with the mid-Columbia Public Utility Districts to meet some of their hydro-system mitigation through hatchery production (CPUD 2002a; CPUD 2002b; DPUD 2002).

In order to make full use of the best science available the program operates on the following general principles ${ }^{1}$ :

1. Monitor, evaluate and adaptively manage hatchery and science programs

[^0]2. Manage hatchery broodstock to achieve proper genetic integration with, or segregation from natural populations
3. Promote local adaptation of natural and hatchery populations
4. Minimize adverse ecological interactions between hatchery- and natural-origin fish
5. Minimize effects of hatchery facilities on the ecosystem
6. Maximize survival of hatchery fish in integrated and segregated programs
7. Develop clear, specific, quantifiable harvest and conservation goals for natural and hatchery populations within an "All-H" (Hatcheries, Habitat, Harvest and Hydro) context
8. Institutionalize and apply a common analysis, planning, and implementation framework
9. Use the framework to sequence and or prioritize actions
10. Hire, train, and support staff in a manner consistent with successful implementation of the program
11. Conduct annual reviews to include peers, stakeholders, and regional managers, and
12. Develop and maintain database and information systems and a highly functional informational web-presence.

The CJHP annual RM\&E activities were focused on six primary field activities to provide data for answering key management questions. These activities included:

1. Rotary screw traps (juvenile outmigration, natural-origin smolt PIT tagging)
2. Beach seine (natural-origin smolt PIT tagging)
3. Lower Okanogan adult fish pilot weir (adult escapement, pHOS , broodstock)
4. Spawning ground surveys (redd and carcass surveys)(VSP parameters)
5. eDNA collection (VSP parameter—distribution/spatial structure)
6. Coded wire tag lab (extraction, reading, reporting)

Additional data compilation activities occurred and were necessary in conjunction with our field efforts to answer the key management questions. These included:

1. Harvest (ocean, lower Columbia, terminal sport, and CCT)
2. Query RMIS for coded wire tag (CWT) recoveries to evaluate strays and stock composition
3. Query PTAGIS for PIT tag returns at mainstem dams and tributaries
4. EDT model estimates for abundance and productivity (from OBMEP)

In-hatchery monitoring/data collection was focused in five areas (see Appendix A):

1. Broodstock collection and bio-sampling
2. Life stage survival
3. Disease monitoring
4. Tagging, marking, and release

## 5. Ladder surplus / pHOS reduction

## Study Area

The primary study area of the CJHP lies within the Okanogan River Subbasin and Columbia River near Chief Joseph Dam in north central Washington State (Figure 1). The Okanogan River measures approximately 185 km long and drains 2,316,019 ha, making it the third largest subbasin to the Columbia River. Its headwaters are in Okanagan Lake in British Columbia, from which it flows south through a series of four lakes before crossing into Washington State at Lake Osoyoos. Seventy-six percent of the area lies in Canada. Approximately 14 km south of the border, the Okanogan is joined by its largest tributary, the Similkameen River. The Similkameen River watershed is 510 km long and drains roughly 756,096 ha. The Similkameen contributes approximately 75\% of the flow to the Okanogan River. The majority of the Similkameen is located in Canada. However, part of its length within Washington State composes an important study area for CJHP. From Enloe Dam (Similkameen rkm 14) to its confluence with the Okanogan, the Similkameen River contains important Chinook pre-spawn holding and spawning grounds. Downstream of the Similkameen confluence, the Okanogan River continues to flow south for 119 km until its confluence with the Columbia River at Columbia River km 853, between Chief Joseph and Wells dams, near the town of Brewster, Washington.

Figure 1. Map of the U.S. portion of the Okanogan River Basin, the Chief Joseph Hatchery (CJH), Winthrop National Fish Hatchery (WNFH), Okanogan adult weir (Weir), Rotary screw trap (RST), and Chinook Salmon acclimation sites. Horizontal coordinate information is referenced to the North American Datum of 1983 (NAD

Similar to many western rivers, the hydrology of the Okanogan River watershed is characterized by high spring runoff and low flows occurring from late summer through winter. Peak flows coincide with spring rains and melting snowpack (Figure 2). Low flows coincide with minimal summer precipitation, compounded by the reduction of mountain snowpack. Irrigation diversions in the lower valley also contribute to low summer flows. As an example, at the town of Malott, Washington (rkm 27), Okanogan River discharge can fluctuate annually from less than 1,000 cfs to over 30,000 cfs (USGS 2005).

The Okanogan Subbasin experiences a semi-arid climate, with hot, dry summers and cold winters. Water temperature can exceed $25^{\circ} \mathrm{C}$ in the summer, and the Okanogan River surface usually freezes during the winter months. Precipitation in the watershed ranges from more than 102 cm in the western mountain region to approximately 20 cm at the confluence of the Okanogan and Columbia Rivers (NOAA 1994). About 50\% to $75 \%$ of annual precipitation falls as snow during the winter months.

For most of its length, the Okanogan River is a broad, shallow, low gradient channel with relatively homogenous habitat. There are few pools and limited large woody debris. Fine sediment levels and substrate embeddedness are high and large woody debris is rare (Miller et al. 2013). Towns, roads, agricultural fields, and residential areas are adjacent to the river through most of the U.S. reaches.

Near its mouth, the Okanogan River is affected by the Wells Dam on the Columbia River, which creates a lentic influence on the lowermost 27 km of the Okanogan River. Water level fluctuates frequently because of operational changes (power generation, storage) at Wells Dam.

## METHODS

## Tag and Mark Plan

HATCHERY SUMMER/FALL CHINOOK. -All summer/fall hatchery-origin Chinook were marked with an adipose fin clip to ensure differentiation from natural-origin fish in the field and in fisheries. Additionally, all summer/fall Chinook raised for the integrated program have been/will be tagged with a CWT (with distinct codes differentiated by release location), which is inserted into the snout of fish while in residence at the hatchery. A batch of 200,000 summer/fall Chinook in the segregated program will receive a CWT, so the presence or absence of a CWT in adipose-clipped fish is a partial diagnostic as to which program an ad-clipped, hatchery-origin fish belongs (Table 1). This will allow for selective efforts in broodstock collection, purse seining, and hatchery trapping activities to be program specific by determining
the presence or absence of a CWT in the field. It was decided that losing some resolution on field differentiation of the segregated and integrated populations was a good tradeoff in order to get the harvest information back from the batch of 200,000 CWT in the segregated program.

Under this strategy, a returning adult from the CJH with an adipose fin clip and CWT would be considered part of the integrated program and either collected for broodstock in the segregated program, allowed to escape to the spawning grounds (if pHOS is within acceptable levels), or removed from the population (for harvest or pHOS management). If a fish has an adipose fin clip but no CWT, then it is assumed from the segregated program (or a stray from another hatchery program) and removed for harvest or pHOS management. In this way, CWTs assist with in-season management of hatchery-origin stocks in the field. The 200,000 segregated fish with a CWT represent about $15 \%$ of the combined segregated $(900,000)$ and integrated ( 1.1 million) hatchery fish with a CWT. If smolt to adult survival and adult holding/migration behaviors are identical, this would mean that $15 \%$ of the subsequent generation of segregated fish would have a segregated parent and would not be consistent with the 'stepping stone' approach. However, segregated fish should spend less time holding at the mouth of the Okanogan and therefore have a lower probability of being collected as broodstock in the purse seine. CWT monitoring from broodstock collections during the first several years of returns will provide insight to this tradeoff.

Coded wire tags are recovered from salmon carcasses during Chief Joseph Hatchery ladder surplus, CCT creel surveys, CCT purse seine, Okanogan weir trapping, and spawning ground surveys in the Okanogan Basin. All recovered CWTs are sent to the Chief Joseph Hatchery coded wire tag lab for extraction, reading, and data upload to the Regional Mark Processing Center operated by the Pacific States Marine Fisheries Commission (PSMFC) ${ }^{2}$. These data are used to develop estimates of total recruitment, rate of return to point of release (homing), contribution to fisheries, survival rates, mark rate, and other parameters, helping inform future management and production decisions within the CJHP.

[^1]Table 1. General mark and tag plan for Chief Joseph Hatchery summer/fall Chinook.

| Mark Group | Target max <br> smolt released | Life-stage <br> released | \% CWT | Adipose <br> Fin-Clip | PIT tag |
| :--- | :--- | :--- | :--- | :--- | :--- |
| Okanogan <br> Integrated | $1,100,000$ |  |  |  |  |
| Similkameen | 400,000 | Yearling | $100 \%$ | $100 \%$ |  |
| Omak Pond | 400,000 | Yearling | $100 \%$ | $100 \%$ | 5,000 |
|  | 300,000 | Sub- <br> yearling | $100 \%$ | $100 \%$ | 5,000 |
| Chief Joseph <br> Segregated | 500,000 | Yearling | $20 \%$ | $100 \%$ | 5,000 |
|  | 400,000 | Sub- <br> yearling | $25 \%$ | $100 \%$ | 5,000 |
| Natural-Origin | RST and <br> Confluence Seine | N/A | $0 \%$ | $0 \%$ | $\leq 25,000$ |

${ }^{1}$ The original plan was to use Riverside Pond for approximately $1 / 3$ of the summer Chinook yearling production, however, to date it has been only been used to acclimate the $10(\mathrm{j})$ spring Chinook because Tonasket Pond has not been rehabilitated for acclimation of spring Chinook.

In addition to the adipose fin-clip and CWT, a subset of hatchery-origin fish will be PITtagged to further assist with fish monitoring efforts in subsequent years. Table 1 represents the general plan at full production.

NatuRAL-ORIGIN FISH TAGGING. -The RM\&E plan called for up to 25,000 PIT tags in juvenile natural-origin summer/fall Chinook parr/smolts. PIT tagging of natural-origin summer/fall Chinook occurred at the rotary screw trap and the juvenile beach seine in 2016. Please see those sections for details.

## Genetic Sampling/Archiving

The CJHP collects and archives genetic samples for future analysis of allele frequency and genotyping of naturally spawned and hatchery Chinook populations. Genetic samples (fin clips) from outmigrant juvenile Chinook were collected during rotary screw trap operations. Samples were preserved in 200-proof molecular grade ethanol and are currently archived at the Chief Joseph Hatchery Science Program office in Omak, WA. Annual tissue collection targets are approximately $n=200$ samples for: (1) natural-origin sub-yearling Chinook handled at the rotary screw trap/beach seine; (2) natural-origin yearling (>130 mm) Chinook handled at the rotary screw trap/beach seine and (3) natural- and hatchery-origin (100 each) Chinook encountered during carcass surveys on the spawning grounds.

The CJHP has also supported requests from Columbia River Inter-tribal Fish Commission (CRITFC) to provide genetic samples (caudal punches) from CJH summer-Chinook broodstock to aid in the development of a Columbia River Parentage Based Tagging (PBT) program. Samples
were preserved on pre-labeled Whatman (GE Healthcare, Pittsburg, PA, USA) cellulose chromatography paper and shipped to CRITFC Lab in Hagerman, ID, USA. Genetic samples will continue to be collected from all hatchery broodstock at CJH.

## Rotary Screw Traps

One 2.4 m and one 1.5 m rotary screw trap (RSTs) were deployed from the Highway 20 bridge near the City of Okanogan (rkm 40) (Figure 3). The RSTs were deployed from April 1 to June 13, 2019. Trapping typically occurred continuously from Sundays at 2000 until Friday at 1300. To continue trapping operations in varying river conditions, traps were operated in one of three trapping configurations: 2.4 m only, 1.5 m only, and both traps operational.

Figure 3. 2.4-m (left) and $1.5-\mathrm{m}$ (right) traps fishing in the Okanogan River. The boat is used by technicians to access the $2.4-\mathrm{m}$ trap. Photo by CCT.

During operation, the trap locations were adjusted in the river to achieve between 5-10 revolutions per minute. The traps were checked every two hours unless a substantial increase in flow ( $\geq 500$ cfs in a 24 -hour period) or debris load occurred, in which case they were checked and cleaned more frequently. All fish were enumerated, identified to species, and life stage, origin (adipose fin present or absent), and disposition (whether the fish was alive or dead), and a subsample of natural-origin Chinook was measured. The fork lengths of the first 10 unmarked Chinook of each 100 encountered in the live well were measured to the nearest mm and
released during each trap check. Steelhead smolts were not measured in order to minimize handling and stress of ESA-listed species. Unmarked (adipose fin present) Chinook captured in the RST that were $\geq 65 \mathrm{~mm}$ total length received a 12 mm full duplex PIT tag, provided water temperatures were below $17^{\circ} \mathrm{C}$. A tissue sample (fin clip) was collected from any yearling unmarked Chinook for future genetic analyses.

EFFICIENCY ESTIMATES. - An estimate of the daily number of juvenile out migrants passing the trap location requires an estimate of the proportion of fish caught by the traps. This was accomplished using mark-recapture methodologies developed by Rayton and Wagner (2006), maintaining continuity with the techniques employed at this RST operation in previous years. This mark-recapture procedure (hereafter referred to as an efficiency trial) was conducted using both natural-origin sub yearling Chinook and hatchery-origin yearling Chinook. Only fish with a fork length of at least 45 mm were used in efficiency trials.

The program did not capture enough subyearling wild juveniles from the screw traps in 2019; therefore, hatchery yearlings from the Omak Pond were used instead. Hatchery fish were marked in 5 gal buckets with Bismarck Brown dye at a concentration of $0.06 \mathrm{~g} / \mathrm{gal}$, held for 1015 minutes with aeration and transported in buckets via a truck for release. Fish were released at night (typically between 0000 and 0330) approximately 1.6 river km upstream by the Oak Street Bridge. Fish were distributed evenly on both sides of the river to allow for equal distribution across the channel. The probability of capture was assumed to be the same for hatchery-origin fish as it was for natural-origin fish.

Because of variable flow and debris conditions, at any given moment, one of several trapping configurations could have been employed, in which either one, both, or neither of the 2.4 and 1.5 m screw traps could be operating. In order to derive an ultimate out migrant estimate, efficiency estimates for all of these configurations were calculated.

Trap efficiency was calculated by the equation

$$
E_{t i}=\sum R_{t i} / \sum M_{i}
$$

where $E_{t i}$ is the trap efficiency for trapping configuration $t$ in sampling period $i, \sum R t i$ is the sum of marked fish that are recaptured in trap configuration $t$ during sampling period $i$, and $\sum M_{i}$ is the sum of marked fish released during the sampling period $i$.

Trap efficiencies were recorded for each individual trap as it operated, and for both traps operating in unison. Trap efficiencies for each individual trap were further refined by including results for each individual trap while both traps were in operation. For example, if 100 marked fish were released, and 1 was recaptured in each trap, each individual trap displays an efficiency of $1 \%$, and the efficiency of both traps operating simultaneously is $2 \%$. This relies on the assumption that the efficiency of each trap is unaffected by whether the other is operating or not.

RST ANALYSIS. - Hourly catch was expanded to an hourly outmigration estimate based on measured trap efficiency by using the Lincoln-Peterson mark-recapture model with a Chapman modifier, which can improve estimates when recapture rates are low (Seber 1982). This model relies on the following assumptions:
1.) All marked fish passed the screw trap or were recaptured during time period $i$
2.) The probability of capturing a marked or unmarked fish is equal
3.) All marked fish recaptured were correctly identified as a marked fish
4.) Marks were not lost or overlooked between time of release and recapture

Total juvenile Chinook emigration was calculated for each trap configuration using a pooled Peterson estimator with a Chapman modification, such that

$$
\widehat{N}=\left[\frac{\left(M_{p}+1\right)\left(C_{p}+1\right)}{\left(R_{p}+1\right)}\right]-1
$$

Where $\widehat{N}$ is total emigration estimate, $M_{p}$ is the total number of marked individuals during the trapping season, $C_{p}$ is the total number of fish caught during the trapping season, and $R_{p}$ is the total number of recaptured fish during the trapping season.

An approximately unbiased estimate of the variance of the population, $\widehat{V}[\widehat{N}]$, is calculated by the equation

$$
\widehat{V}[\widehat{N}]=\frac{\left(M_{p}+1\right)\left(C_{p}+1\right)\left(M_{p}-R_{p}\right)\left(M_{p}-R_{p}\right)}{\left(R_{p}+1\right)^{2}\left(R_{p}+2\right)}
$$

The precision of the population estimates was assessed by including $95 \%$ confidence intervals calculated by the equation

$$
\widehat{N} \pm 1.96 \sqrt{\widehat{V}[\widehat{N}]}
$$

Estimates and confidence intervals were calculated for all trapping configurations and then summed to generate an overall estimate for the trapping season. During periods when neither trap was operating, an estimate was calculated based on the average catch of an equal time period immediately prior and following the inoperable period. For example, if no traps were operable on April 30, catch for that day would be estimated to be the average of total catch on April 29 and May 1.

Trapping efficiency and outmigration estimation was also examined using a smolt abundance estimator provided by WDFW and developed for its efforts in the Wenatchee River
that incorporates stream flow and weights efficiency trials according to the number of released fish (Murdoch et al. 2012; Ryding 2000).

Juvenile Beach Seine/PIT tag effort
Portions of the following text describing the methods were taken directly from a draft DPUD report (DPUD 2014).

Beach seining took place from May 14-16 in the Okanogan River side channel just upstream of Riverside and from May 28 to June 26 in the area near the confluence of the Okanogan and Columbia Rivers. Efforts at the confluence were focused on beaches along the North bank of the Columbia River, downstream of the mouth of the Okanogan ( $48^{\circ} 6^{\prime} 12.46$ " N , $119^{\circ} 44^{\prime} 35.48$ "W) (Figure 4). This area is known as Gebber's Landing. This location provided reasonable catch rates, limited bycatch, and provided suitable substrates (limited debris loads/underwater snags) for efficient sampling. Juvenile Chinook from this location were likely primarily fish originating from the Okanogan River based on results from stable isotope analysis conducted in 2018.

Figure 4. Seining locations downstream (Gebber's Landing) and upstream (Washburn Island) of the confluence.

A single beach seine ( $30.49 \mathrm{~m} \times 3.05 \mathrm{~m}$ with a $28.32 \mathrm{~m}^{3}$ 'bag'; Christensen Net Works, Everson, WA) was used to capture fish. Netting was Delta woven 6.4 mm mesh with "fish-green" treatment. Weights ( $3-5 \mathrm{~kg}$ ) were attached to each end of the seine to help keep it open during retrieval.

To capture fish, one end of the seine was tied off to an anchor point onshore, while the other was towed out by boat until the seine was stretched perpendicular to shore. The boat would then pull the seine upstream and return to shore, causing the seine to form a semi-circle intersected by the shoreline (Figure 5). The seine bridle was handed from the boat to a shore crew that would retrieve the seine. Juvenile Chinook were transferred to a 10-gallon tub filled with river water and transferred to a nearby floating net pen. Handling/holding time in the tub
was generally <15 minutes. Floating net pens were approximately $5 \mathrm{~m}^{3}$ and consisted of a PVC pipe frame covered with black $19.1-\mathrm{mm}$ and $3.2-\mathrm{mm}$ mesh. The mesh allowed for adequate water exchange, retained juvenile Chinook, and prevented the entrance of predators. Noticeable bycatch, most commonly three-spine stickleback (Gasterosteus aculeatus) were released from the seine without enumeration. Any bycatch inadvertently transferred to the floating net pen were later sorted and released during tagging (untagged). On May 28 and 29, fish captured in the beach seine were immediately tagged on the river shore and released after recovery from anesthesia.

Figure 5. Juvenile beach seine being retrieved by CCT staff near the confluence of the Okanogan and Columbia Rivers.

In most circumstances, juvenile Chinook were held 24 hours prior to tagging to assess capture/handling effects. Occasionally, due to staff availability or other complicating circumstances, fish were held for two days or released shortly after recovery from anesthesia. Chinook $\geq 65 \mathrm{~mm}$ were tagged with a full duplex 12 mm PIT tag, and Chinook between 65 and 50 mm were tagged with a full duplex 9 mm PIT tag. After tagging, fish were returned to a floating net pen for 24 hours post-tagging to assess tag loss and tag application/handling
mortality rates. Fish were then released to the Columbia River (Wells Pool) several hundred meters downstream of their capture location.

TAGGING PROCEDURES. - Tagging was conducted by CCT staff with support from USGS using a mobile tagging station (Biomark, Co., Boise, ID, USA). The tagging station consisted of an approximately $1 \mathrm{~m}^{2}$ aluminum work surface with a trough for holding fish during the tagging process as well as all the necessary electronics (computer, tag reader, and antenna) needed for tagging. Water was pumped directly from the river using a $1 / 4$ horsepower pump. When tagging water temperatures were $>17{ }^{\circ} \mathrm{C}$, water was replaced in the trough with cooler water from the river. A solution of 4.0 g Tricaine methanesulfonate (MS-222) per 1 L of water was used to anesthetize fish prior to tagging. The applied concentration of MS-222 would sedate fish to the desired level of stage- 2 anesthesia in approximately 3 to 4 minutes. All fish were tagged within 10 minutes of the initial exposure. Recovery time was approximately 1 to 2 minutes.

The tagging location had two net pens: one containing the fish to be tagged, and an empty pen for holding fish post-tagging. Fish to be tagged were collected from the respective net pens using a dip net and placed into an 18.9 L bucket of water. Up to 40 fish at a time were then transferred from the bucket using a smaller dip net and placed into the trough containing the anesthetic solution.

Fish were tagged with 12.5 mm 134.2 kHz ISO PIT tags using pre-loaded, 12-gauge hypodermic needles (BIO12.BPLT) fitted onto injection devices (MK-25). 12.5 mm PIT tags were used to maximize detection at downstream locations, particularly the Rocky Reach Juvenile Bypass and the Bonneville Dam Corner Collector, although 9 mm PIT tags were used in fish. Detection efficiencies at both of the former sites would dramatically suffer when using the smaller PIT tags available. The tagging crew consisted of one fish sorter, one tagger and one data collector. The data collector interrogated the tag in each tagged fish, recorded its fork length and noted any anomalies. Tagged fish were transferred to the recovery/holding pen via a PVC pipe with flowing water.

Data collected during tagging were stored using PITTAG4 (P4) software (Pacific States Marine Fisheries Commission). After completion of the tagging events, tag files were consolidated, uploaded to PTAGIS (www.ptagis.org).

FISH RELEASES. -Tagged fish were released the morning after they had been tagged. Prior to release, the net pen was opened, and all observed mortalities and moribund fish were removed. Once the mortalities were removed, expelled (shed) tags from live fish were recovered from the mesh floor via a powerful magnet. After that was completed, the net pen was tilted to allow the fish to volitionally exit. PIT tags were recovered from dead/moribund fish, the associated tag codes were marked as "Mortalities" in the tag files and the tag codes were deleted. Carcasses of summer Chinook were returned back to the river.

## Lower Okanogan Adult Fish Pilot Weir

The Okanogan adult fish pilot weir (herein referred to as the 'weir') was in its eighth year of design modifications and testing in 2019. Continued operation and improvements to the weir are a central part of CCT's strategy for the successful implementation of the CJHP summer/fall Chinook Salmon (Oncorhynchus tshawytscha) programs. Pilot weir test results are essential for updating key assumptions, operations, and design of the weir.

Objectives for the pilot weir in 2019 included:

1. Install the weir in early July and operate until late September under allowable flow conditions ( $<3,000 \mathrm{cfs}$ ) and temperature ( $<22.5^{\circ} \mathrm{C}$ );
2. Document environmental effects of the weir through collection of physical and chemical data in the vicinity of the weir;
3. Test weir trapping operations and the Whooshh ${ }^{\text {TM }}$ fish transport system including live Chinook capture, handling and release;
4. Direct observations and fish counts for estimating species composition, abundance, health, and timing to inform management decisions and future programoperations;
5. Collect NOR and/or HOR brood stock at the weir and transport safely to the CJH;
6. Test the weir configuration, including the location of the trap box, to meet the program's biological and brood-take goals
7. Test fish entrainment through the trap entrance chute and into the trap box

The lower Okanogan fish weir was installed approximately 1.5 km downstream of Malott, WA ( $48^{\circ} 16^{\prime} 21.54 \mathrm{~N} ; 119^{\circ} 43^{\prime} 31.98 \mathrm{~W}$ ) in approximately the same location as previous years. Weir installation began on July 15th at a river flow of 1,540 cfs. and was completed with the underwater video system on July $19^{\text {th }}$. An aluminum trap was installed near the center of the channel at the downstream end of the deep pool in the thalweg of the channel (Figure 6). The trap was 3 m wide, 6 m long and 3 m high. A fifteen-foot aluminum accelerator chute was installed at the downstream trap gate. The wings of the weir stretched out from either side of the chute towards the riverbanks, angling downstream in a slight $V$ configuration. The wings consisted of steel tripods with aluminum rails that supported the 3 m long Acrylonitrile butadiene styrene (ABS) pickets. Each panel was zip-tied to the adjacent panel for strength and stability. Sandbags were placed between panels when needed to fill gaps that exceeded the target picket spacing. Picket spacing ranged from 2.5 to 5.1 cm ( 1 to 2 inch ) in 1.2 cm (half-inch) increments (Figure 7). Pickets were manually forced into the river substrate upon deployment and then as needed to prevent fish passage under the weir.

The river-right wing consisted entirely of 2.5 cm picket spacing (Figure 7). A 3 m gap between the last panel and the right shoreline remained to allow for portage of small vessels around the weir. This was a very shallow gravelly area and under most flow conditions it did not appear to be a viable path for adult salmon passage. However, a set up floating panels that were attached to the substrate extended from the last panel to the river-right shore to limit escapement via this route. The river left wing had variable picket spacing to accommodate non-Chinook fish passage through the pickets. The primary objective of the wider picket spacing was to allow Sockeye ( $O$. nerka) to pass through the weir and reduce the number of Sockeye that would enter the trap. River left was selected for this spacing to better accommodate observation/data collection regarding successful passage of smaller fish through the panels. In past years CCT has observed jack and even adult Chinook passing through the 6.4 and 7.6 cm picket spacing panels. These picket spacing panels were replaced with 5.1 cm picket spacing panels during deployment to reduce the escapement of smaller hatchery Chinook but still allow Sockeye to pass through these panels.

Figure 6. Lower Okanogan adult fish pilot weir, 2019. Photo taken in late- August.

Figure 7. Conceptual diagram of picket (ABS pipe) spacing within each panel (or set of 5 panels) at the Lower Okanogan adult fish pilot weir. A 15 ft entrance chute was installed at the lower trap gate in 2019.

Physical and chemical data were collected in the vicinity of the weir including the water depth ( ft ) inside the trap, water velocity ( $\mathrm{ft} / \mathrm{sec}$ ) upstream, downstream and in the weir trap, dissolved Oxygen (mg/L), total dissolved solids (TDS)(ppm), turbidity (NTU), temperature $\left({ }^{\circ} \mathrm{C}\right.$ ), discharge (cfs) and head differential (cm). Temperature and discharge were taken from the online data for the USGS gauge at Malott (http://waterdata.usgs.gov/wa/nwis/uv?site no=12447200). When river temperature exceeded $22.5^{\circ} \mathrm{C}$, trapping operations ceased and weir pickets on panels adjacent to the trap on both sides were raised to allow for unrestricted fish passage.

Five-minute tower observations were conducted at least three times a day, in the morning (0600-0800), early afternoon (1200-1400) and evening (1700-1900) and an estimate of the number fish observed was recorded. Ten-minute bank observations were conducted about 0.8 river km. downstream of the weir, around two pools, at least twice a day, in the morning and afternoon. An estimate of the number of fish observed below the weir was recorded. Algae and debris were cleared off of the weir at least once per day generally in the morning (0800-1000) or afternoon (1200-1400), depending on when fish were migrating. Dead fish on the upstream side of the weir were enumerated, identified to species and the presence and extent of injuries were noted. The tail was cut off of each mortality before they were tossed downstream of the weir so that they would not be double counted
during surveys.
Weir efficiency, a measure of the proportion of total spawning escapement encountered by the weir, was calculated by the equation;

$$
X=\frac{W_{T}}{T}
$$

where $X$ was weir efficiency, $W_{T}$ was the number of adult summer/fall Chinook encountered in the weir trap including released fish, and $T$ was the total summer/fall Chinook spawning escapement for the Okanogan River Basin.

Weir effectiveness was a measure of the proportion of the adult hatchery Okanogan summer/fall Chinook run encountered in the weir trap, becoming available for removal from the population as a form of adult fish management. It was calculated by the equation;

$$
Y=\frac{W_{H}}{W_{H}+H O S}
$$

where $Y$ is weir effectiveness, $W_{H}$ is the number of adult hatchery origin fish encountered in the weir trap, and HOS is the total number of hatchery origin spawners.

Trapping operations were conducted 24 hours/day, 7 days/week, under allowable temperature conditions ( $\leq 22.5^{\circ} \mathrm{C}$ ) for the season. Trapping operations were suspended for the majority of the season, from July 22-August 25 and August 28-September 8. The last day of trapping was on September 11th. When fish entered the trap during an active trapping session, the downstream gate was closed, and fish were identified and either released or collected for brood.

Nine natural-origin and two hatchery-origin Chinook were collected from the weir trap from August 26-27 and September 9-11, transported to a 2,500-gallon hatchery truck via a rubber boot. The fish were then transported approximately 32 km to Chief Joseph Hatchery where they were held in the brood stock raceways until spawning in October. The Whoooshh ${ }^{\text {TM }}$ fish transport system was not deployed in 2019 because by the time we were able to trap and collect brood for the program, only 10 adults were needed, which did not justify the program's need to setup the system.

In recent years, mark-recapture studies were performed at the weir trap to assess handling mortality at the weir as well as recovery bias of carcasses on the spawning grounds. All natural-origin Chinook that were trapped and destined for release upstream, were anesthetized with electronic anesthetic gloves, measured, and inserted with a floy tag. After the fish were tagged, they were released over the crowder and into the upstream side
of the trap where they recovered before they exited through the trap gates on their own volition. Unfortunately, there were little to no carcasses recovered on the spawning grounds after the tagging effort, so the program decided not to conduct the study in 2018 until a larger number of fish were captured in the trap (i.e., higher weir efficiency).

## Spawning Ground Surveys

The objectives for spawning surveys were to:

1. Estimate total spawning escapement based on the number of Chinook redds per reach
2. Estimate the proportion of natural spawners composed of hatchery-origin recruits (pHOS)
3. Estimate pre-spawn mortality and mean egg retention for wild- and hatchery-origin spawners
4. Determine the origin (rearing/release facility) of hatchery-origin spawners (HOS) in the Okanogan and estimate the spawner composition of out-of-population and out-ofESU strays (immigration)
5. Estimate out-of-population stray rate for Okanogan hatchery Chinook and estimate genetic contribution to out-of-basin populations (emigration)
6. Determine age composition of returning adults through scale analysis
7. Monitor status and trends of demographic and phenotypic traits of wild- and hatchery-origin spawners (age-at-maturity, length-at-age, run timing, SAR)

## REDD SURVEYS

A primary metric used to monitor the status and trends of salmonid populations is spawning escapement. Estimates of spawning escapement can be calculated based on redd counts and expanded by sex-ratios (Matthews and Waples 1991, Gallagher et al. 2007). This requires intensive visual survey efforts conducted throughout the spawning area and over the course of the entire spawning period. Visual redd surveys were conducted to estimate the number of redds per survey reach from the mouth of the Okanogan River to Zosel Dam (river km 124); the Similkameen River from its confluence with the Okanogan River upstream to Enloe Dam (river km 14); and in the mainstem Columbia River from the mouth of the Okanogan River upstream to Chief Joseph Dam (Table 2). Weekly surveys were timed to coincide with spawning in the basin, generally beginning the last week of September or the first week of October and ending approximately the second week of November. Redds were counted using a combination of fixed-wing aerial flight surveys and inflatable raft float surveys.

Aerial surveys occurred once weekly throughout the spawning season, each covering the entire survey area. Aerial surveys were flown at low elevation and at moderate speeds to
accommodate visual identification of redds. From the aircraft, a trained observer recorded the number and GPS coordinates of all new redds as the plane passed overhead. All data were recorded directly into a YUMA rugged computer tablet (Trimble Navigation, Ltd.). Aerial surveys were primarily used to document redds in areas inaccessible to rafts, or in areas of low redd densities, such that they did not warrant weekly float surveys. All data points were visualized in ArcGIS (ESRI, Inc.), and quality controlled to ensure that redd counts were not duplicated during float surveys. Aerial surveys also served a secondary function of informing research crews where to focus weekly carcass recovery efforts (see below section on Carcass Surveys).

Float surveys occurred once daily, 5 days per week throughout the spawning season. Float surveys consisted of three 2-person teams using inflatable rafts to count redds while floating downstream. Each team was responsible for covering one-third of the river width, (1) left bank, (2) center, and (3) right bank. Each individual redd was counted and its position recorded directly into a YUMA rugged computer tablet (Trimble Navigation, Ltd.).

Table 2. Reach names and locations for the Okanogan and Similkameen for summer/fall Chinook Salmon spawning and carcass surveys.

| Stream | Code | Reach Description | River km |
| :---: | :---: | :---: | :---: |
| Okanogan | O1 | Mouth to Malott Bridge | $0.0-27.0$ |
|  | O2 | Malott Bridge to Okanogan Bridge | $27.0-41.8$ |
|  | O3 | Okanogan Bridge to Omak Bridge | $41.8-49.1$ |
|  | O4 | Omak Bridge to Riverside Bridge | $49.1-65.1$ |
|  | O5 | Riverside Bridge to Tonasket Bridge | $65.1-90.9$ |
|  | O6 | Tonasket Bridge to Zosel Dam | $90.9-124.0$ |
| Similkameen | S1 | Mouth to Oroville Bridge | $0.0-8.0$ |
|  | S2 | Oroville Bridge to Enloe Dam | $8.0-14.0$ |
| Canada | Cx | TBD | TBD |

All redds were classified as either a:

1. Test-redd (disturbed gravel, indicative of digging by Chinook, but abandoned or without presence of Chinook; generally, this classification is reserved for early season redd counts before substantial post-spawn mortalities have occurred as indicated by egg-voidance analysis of recovered carcasses). Test-redds do not contribute to annual redd counts.
2. Redd (disturbed gravel, characteristic of successful Chinook redd construction and/or with presence of Chinook).
Redds per reach were calculated for each week as the combined number of new redds counted during aerial- and float-surveys for a given week. Post-season analysis consisted of summing the combined aerial- and float-survey weekly redd totals to calculate annual redd totals per reach, and per total survey area. Estimated total spawning escapement was then calculated by multiplying the total redd count by the expansion factor for the current year ( 2.300 for 2019). The expansion factor $=1+$ the number of males per female as randomly collected for broodstock at Wells Dam (1.300:1.000 in 2019). Assumptions include:

Assumption I - Each redd was constructed by a single female Chinook, and each female Chinook constructed only one redd

Assumption II - The male: female ratio on the spawning grounds was the same for wild- and hatchery-origin Chinook, and is equal to the male: female ratio as randomly collected for broodstock at Wells Dam

Assumption III - Every redd was observable and correctly enumerated

## Escapement into Canada

In previous years, video systems operated by OBMEP and located in the fishways of Zosel Dam allowed observation of salmonids passing over Zosel Dam and potentially into the British Columbia portion of the Okanagan River Basin. For detailed methods within a particular year please see the Okanogan Basin Monitoring and Evaluation Program (OBMEP) annual reports posted at (http://www.colvilletribes.com/obmep_publications.php). However, in 2019 no video monitoring occurred. Therefore, any information regarding Chinook passage at Zosel Dam and/or escapement into the Canadian portion of the Okanagan basin in 2019 is extremely limited and are based primarily on in-stream PIT array data and anecdotal observations.

## CARCASS SURVEYS

Carcass surveys provide important biological samples for evaluation of hatchery- and natural-origin fish on the spawning grounds, including:

1) Spawner composition
a. pHOS
b. out of population hatchery strays (immigration)
c. spatial distribution of natural- and hatchery origin spawners
2) Fish size
3) Sex -ratio
4) Age structure (CWT and scale analysis)
5) Pre-spawn mortality (i.e., egg retention)

The target sample size for carcass recovery efforts is $20 \%$ of the spawning population within each reach (Hillman et al. 2014). Carcass recovery efforts occurred simultaneously with redd float surveys, although carcass efforts also occurred once a week during August and September on the Similkameen River as well. These surveys assessed potential prespawn mortality that occurred for those fish that held in the cooler waters of the Similkameen River before spawning began in October. Recovered carcasses were transported within inflatable rafts downstream until a suitable site was found for processing. If a carcass was too degraded to sample for biological data, it was returned to the river without sampling. All adipose absent carcasses were assumed to be of hatchery-origin, and all carcasses displaying an intact adipose fin were assumed to be of natural-origin ${ }^{3}$. Origin was later verified by results from the WDFW scale lab analyses. Biological data collected from carcasses included sex, fork length (FL) and post-orbital hypural length ( POH ) to the nearest cm , and estimated egg retention for all females ( 0 to 5,000 max; visually estimated). All eggs that were not estimated to be within a carcass were assumed to have been successfully deposited. Any female carcass containing an estimated 5,000 eggs were considered a pre-spawn mortality. Forceps were used to remove five scale samples from all natural-origin Chinook. Scales were adhered to desiccant scale cards for preservation and identified by sample number and sample date. At the conclusion of spawning season, scales were sent to WDFW for post-hoc age analysis. Age analysis data were used to assess age-at-return (run-reconstruction) and combined with biological data to assess length-atage. All Chinook were scanned for passive integrated transponder (PIT) tags and all PIT detections were recorded and later uploaded to PTAGIS. Carcasses were scanned with a T-wand (Northwest Marine Technology, Inc., Shaw Island, WA USA) for coded wire tags (CWT). If present, the snout portion was removed and individually bagged and labeled with species, origin, FL, river of recovery and date. After sampling each carcass, the caudal fin was removed before the carcass was returned to the river to avoid resampling on subsequent surveys. All data collected in the field were input directly into a YUMA rugged computer tablet (Trimble Navigation, Ltd.). Weekly carcass recovery totals were summed post-season to calculate annual carcass recovery totals per reach and per survey area.

Some key assumptions for carcass surveys included:
Assumption I - All carcasses had the same probability of being recovered on the spawning grounds (despite differences in sex, origin, size, or spawning location)

[^2]Assumption II - The diagnostic unit in which a carcass is recovered is the same as the reach in which the fish spawned

Assumption III - Sampled carcasses are representative of the overall spawning composition within each reach

## pHOS and PNI

pHOS was first calculated using the straightforward method of calculation for the population-level pHOS by simply dividing the number of hatchery-origin spawners by the total spawners, such that:

$$
p H O S=\frac{H O S_{O}}{H O S_{O}+\mathrm{NOS}_{O}}
$$

where $H O S_{O}$ is the total recovered hatchery-origin carcasses and $N O S_{O}$ is the total recovered natural-origin carcasses. This simple algorithm does not account for assumed deficiencies in hatchery fish effectiveness (i.e., relative reproductive success) nor does it account for spatial variation in pHOS and unequal sampling effort across reaches. For example, reach S1 tends to have a higher pHOS than other reaches because the Similkameen acclimation site is located in the reach. Likewise, the probability of recovering carcasses in low density spawning reaches is lower than in reaches with high density spawning. We have attempted to account for each of these factors.

Relative reproductive success has not been estimated for summer/fall Chinook in the Okanogan. One of the key assumptions in the In-Season Implementation Tool was that firstgeneration hatchery fish are less effective natural spawners than natural-origin fish. Currently, the hatchery fish effectiveness assumption for the Okanogan population is that first-generation hatchery-origin spawners are $80 \%$ as effective as natural-origin fish as contributing genes to the next generation ${ }^{4}$ This assumption is based on research conducted by Reisenbichler and McIntyre (1977) and Williamson et al. (2010). Therefore, the pHOS calculation was amended in 2013 to account for the reduction in hatchery spawner effectiveness, such that:

$$
\text { Effective } p H O S=\frac{0.8 \mathrm{HOS}_{O}}{0.8 \mathrm{HOS}_{O}+\mathrm{NOS}_{O}}
$$

Further refinement of the pHOS calculation was needed to account for non-random sampling of carcasses and variable pHOS across reaches. This was done by weighting each reach's overall contribution to system-wide pHOS according to the overall proportion of summer/fall Chinook redds that occurred within that reach.

First, the proportion of redds that corresponded to each reach was calculated by the equation:

[^3]$$
r e d d_{p, r}=\frac{r e d d_{r}}{r e d d_{O}}
$$
where, $r e d d_{r}$ is the number of documented redds that occur within reach $r$, redd $d_{o}$ is the total number of redds documented in the U.S. portion in the Okanogan River Basin, and redd $d_{p, r}$ is the proportion of total redds that were documented in reach $r$.

Next, Effective pHOS was calculated separately for each sampled reach, $r$, so that:

$$
p H O S_{r}=\frac{0.8 H O S_{r}}{0.8 H O S_{r}+\mathrm{NOS}_{r}}
$$

where $\mathrm{pHOS}_{r}$ is the Effective pHOS calculation for reach $r$, and $\mathrm{HOS}_{r}$ and $\mathrm{NOS}_{r}$ are the total recovered carcasses of hatchery- and natural-origin within that reach. Finally, Effective pHOS was corrected for the proportion of redds in each reach to determine an adjusted Effective pHOS, such that:

$$
\text { Effective } p H O S=\sum_{i=1}^{n} p H O S_{r}\left(\text { redd }_{p, r}\right)
$$

where $n$ is the total number of sampled reaches that compose the Okanogan River Basin. These calculations assumed that sampled carcasses were representative of the overall spawning composition within each reach; that no carcasses were washed downstream into another reach; that all carcasses had an equal probability of recovery; and that all fish within origin types had equal fecundity. While it is unlikely that all of these assumptions were correct, the modified calculation results in a better representation of the actual census pHOS .

PNI was calculated as:

$$
P N I=\frac{p N O B}{\text { Effective } p H O S+p N O B}
$$

where $p N O B$ was the proportion of broodstock that were natural-origin Okanogan returns, and Effective pHOS was the reach weighted effective pHOS defined previously. To determine an Okanogan specific pNOB , we applied the results of a radio tracking study, which estimated that $90 \%$ of the natural-origin fish detected near the mouth of the Okanogan River in 2011 and 2012 ended up spawning in the Okanogan Basin (Mann and Snow 2013). Therefore, we assumed that $90 \%$ of the NOB collected in the purse seine (2010-2013) was of Okanogan origin.

In years prior to 2010 all of the broodstock for the Similkameen program were collected at Wells Dam. That program strived for $100 \%$ pNOB and did achieve $>95 \%$ pNOB in 7 of the last 8 years (Hillman et al. 2014). However, the Wells Dam broodstock collection efforts composited natural-origin fish from the Okanogan and Methow populations as well as fish originating from
downstream populations ${ }^{5}$. We made a correction for non-Okanogan NOB for all years when Wells Dam was used for brood collection using the formula:

$$
\text { Adjusted Wells Dam } p N O B=\text { Wells Dam } p N O B *\left(\frac{\text { Okanogan NOS }}{\text { Okanogan NOS }+ \text { Methow NOS }}\right)
$$

where the Adjusted Wells Dam pNOB was estimated based on the proportion of natural-origin spawners (NOS) that were in the Okanogan compared to the Methow for that particular year. This correction was made for a portion of the broodstock in 2010 and 2011 and all of the broodstock previous to 2010. This correction did not account for stray NORs from downstream populations or NORs that would have remained in the Columbia River above Wells Dam. Although the radio tracking study provides an estimate of this for 2011 and 2012, there was uncertainty regarding the applicability of the radio tracking data for years prior.

## Origin of Hatchery Spawners

Snouts from adipose fin clipped fish were removed, individually labeled, frozen, and delivered to the Chief Joseph Hatchery coded wire tag lab for CWT extraction and reading. The Regional Mark Information System (RMIS; http://www.rmis.org/rmis) was queried in March 2020 to assess the rearing facility of hatchery-origin Chinook recovered on the Okanogan spawning grounds, the in-to-basin stray rate, and the out-of-basin stray rates. RMIS data queries are described in detail in the 2013 CJHP Annual Report (Baldwin et al. 2016).

## Smolt-to-Smolt Survival and Travel Time

Survival and travel time were assessed using the Data Acquisition in Real Time (DART) website analysis tools. DART calculates a survival estimate using a Cormack Jolly Seber mark recapture model, for full details on the analysis methods please see the DART website (http://www.cbr.washington.edu/dart/query/pit sum tagfiles). Each CJH release group with PIT tags were queried for survival from release to Rocky Reach Dam Juvenile bypass (RRJ) and McNary Dam Juvenile bypass (MCN). Although some recaptures were obtained further downstream than McNary Dam, survival through the entire hydropower system to Bonneville Dam could not be generated because there were not enough recaptures downstream to estimate the recapture probability. Survival estimates and travel time for nearby hatcheries and the wild summer Chinook captured in the RST and beach seine were also analyzed for comparison purposes.

Survival estimates are 'apparent survival' because they were not adjusted for residuals, tag failure, tag loss (shedding), or other factors which could result in fish not dying but not being detected at a downstream location. Due to these factors, actual survival would be higher than the apparent survival estimates provided in this report.

[^4]Migration timing from release to the lower Okanogan River was determined using a query of the PTAGIS database (https://www.ptagis.org/data/quick-reports/small-scale-sitedetections) to determine the timing of PIT tag detections from releases of Summer Chinook at Omak Pond. A PIT tag group from the Similkameen Pond was released in 2019. The lower Okanogan River PIT tag interrogation site (OKL) is located at rkm 25 and is within 2 km of the inundation effects of Wells Dam.

## Smolt-to-adult Return

The smolt to adult return rate (SAR) was calculated using two different methods, PIT tags and coded-wire tags (CWT). For PIT tags, SAR was calculated for adult fish (age 4-6) from release, back to Bonneville and Wells dams using the formula:

$$
S A R=\frac{\# \text { PIT tags detected in adult ladders at dam } x}{\# \text { PIT tags released }}
$$

A correction was then applied to the SAR to account for adult fish harvested before reaching each dam. Standard harvest rates for each return year were applied based on harvest summaries for indicator stocks generated by the Technical Advisory Committee of US v Oregon.

The SAR for CWT was estimated as:

$$
S A R=\frac{\text { expanded CWT recoveries }}{C W T \text { released }}
$$

where expanded CWT recoveries included estimated expanded recoveries on the spawning grounds, at hatcheries and in fisheries. Two expansions were applied. First the number of recoveries was expanded to account for the proportion of the release group that wasn't tagged. For example, with a $99 \%$ CWT mark rate the recoveries would be increased by $1 \%$. Second, the recoveries were expanded based on the proportion of the population that was sampled. For example, if carcass surveys recovered $20 \%$ of the estimated spawners, then the number of CWT recoveries was expanded by $80 \%$. The number of CWT fish released were simply the hatchery release data including all tag codes for CWT released fish (CWT + Ad Clip fish and CWT-only fish).

## Coded Wire Tag Lab Analysis

Coded wire tags (CWT) from broodstock, ladder surplus, purse seine harvest, creel and spawning ground surveys were extracted, read, and reported in the Chief Joseph Hatchery Lab from December 2019 to February 2020. The snouts were then interrogated for the presence of a CWT by using a V-reader or T-wand. After positive detection, the snout was cut bilaterally into symmetrical portions keeping the half that indicated detection and discarding the other half into
the snout bag from which it came. This process was then repeated until only a small piece of tissue containing the CWT remains. The final piece of tissue was then smeared on a cutting mat exposing the CWT, then placed on its corresponding snout card and finally on to a cafeteria tray (groups of $\sim 25$ tags) to be read under a microscope.

Extracted tags were removed from the tray one-by-one to be cleaned, recorded, and read. The CWT was cleaned by wetting a lint free cloth and rolling the tag between a finger and cloth to remove all remaining tissue. The CWT was attached to a Northwest Marine Technologies (NMT) magnetic pencil and inserted into a jig to be read under a LCD microscope with the aid of an illuminator. Biological data was transcribed from the snout card to a final CWT datasheet. The CWT was attached to this datasheet with tape after the six-digit code was read. Information from the datasheet was transferred to an excel workbook which contains all applicable CWT code combinations.

CWTs were expanded based on their tag loss and sample rate to estimate total catch contribution for a specific fishery. For each fishery, every CWT recovered and decoded was grouped according to their tag code with the total number of CWTs recovered from that release group, (e.g., tag code 200108 was recovered 10 times for a fishery/location (tag group 1). (See formula 1 below). Tag group 1 is then divided by the sum of all recovered/decoded CWTs for that specific fishery. This value was multiplied by the sum of all lost and scratched tags with tag group 1 being added to the end of the calculation. This provides an adjustment factor for lost and scratched tags for every unique tag code by hatchery of origin. Mark rates are typically high ( $\sim 99 \%$ ) for most Upper Columbia River release groups, however it is important to account for missing tags or tags that were shed during the fish's lifecycle. (See formula 2 below). Taking the adjustment factor for lost and scratched tags and multiplying it by the tag loss rate (tag loss rate can be found at www.RMPC.ORG) provides an adjustment for missing tags. These adjustments (lost/scratched/missing) can be summed together to provide total catch contribution for a fishery that was sampled at 100 percent. (See formula 3 below). When sampling occurred at less than 100 percent the adjustment total is divided by the sample rate to calculate the expanded number of fish for each release group.
(1) Adjustment for Lost/scratched tags:

$$
\left.C W T_{\text {Adjustment }=\left(T_{\text {Tag }}^{\text {group } 1} 1\right.} / \Sigma \text { Total tags }\right) *\left(\sum \text { Lost }+ \text { scratched Tags }\right)+\text { Tag }_{\text {group } 1}
$$

(2) Adjustment for tag loss:

(3) CWT expansion
$C W T_{\text {Adjustment }=\left\{\left(\text { Tag }_{\text {group } 1} / \Sigma \text { Total tags }\right) *\left(\sum \text { Lost }+ \text { scratched } \text { Tags }\right)+\text { Tag }_{\text {group } 1}\right\} *(\text { Tag loss Rate })}$

## Sample Rate

Finally, after accounting for the mark rate of each group, the remaining ad-clip, no-CWT fish were assigned to the CJH segregated group.

## ReSULTS

## Rotary Screw Traps

The rotary screw traps captured 4,170 Chinook juvenile out migrants, including 290 hatchery-origin and 3,880 natural-origin. The mean length of Chinook increased throughout the trapping season 873 natural-origin smolts were large enough ( $>60 \mathrm{~mm}$ ) to PIT tag after capture at the screw trap (Figure 10). No natural-origin fish were captured that were likely yearling Chinook.

Following Chinook, the next most abundant species captured in the RST was Sockeye (Table 3). Thirty-two adipose fin present ${ }^{6}$ steelhead and 902 adipose fin absent (hatcheryorigin) steelhead were removed from the trap and released immediately into the river. There was one juvenile steelhead mortality at the trap resulting in a $1 \%$ juvenile trapping and handling mortality rate for steelhead. The encounter of 902 adipose clipped and 32 adipose present (assumed natural-origin) and mortality of zero (0) assumed natural-origin steelhead are within the take limits identified in the authorizing ESA Section 10(a)(1)(A) Permit for the rotary screw trap operation (Permit 16122).

Figure 8. Daily natural-origin sub-yearling Chinook catch within an 8 foot and 5 foot the Okanogan River in 2019.

[^5]

Figure 9. Natural-origin sub-yearling Chinook size distribution ( $\mathrm{n}=1,003$ ) from the rotary screw traps on the Okanogan River in 2019. Boxes encompass the $25^{\text {th }}$ to $75^{\text {th }}$ percentiles of measured fish, points represent statistical outliers, and the mid-line in the box is the median fish length. FL = fork length in millimeters (mm).

Table 3. Number of juvenile fish trapped at the Okanogan River rotary screw traps in 2019.

| Species | Total Trapped |
| :---: | :---: |
| Bluegill | 14 |
| Bridgelip Sucker | 38 |
| Common Carp | 0 |
| Longnose Dace | 8 |
| Northern Pikeminnow | 279 |
| Largemouth Bass | 0 |
| Sculpin (Cottus spp.) | 4 |
| Smallmouth Bass | 16 |
| Three Spine Stickleback | 15 |
| Peamouth | 0 |
| Redside shiner | 0 |
| Crappie (Pomoxis spp.) | 0 |
| Bullhead (Ameiurus spp.) | 1 |
| Yellow Perch | 59 |
| Yellow Bullhead | 2 |
| Channel Catfish | 1 |
| Unknown Dace | 2 |
| Non-salmonid total | 439 |
| Adipose Clipped steelhead | 902 |
| Adipose Present steelhead | 32 |
| Hatchery Chinook | 290 |
| Sockeye | 961 |
| Wild Chinook Subs | 6635 |
| Wild Chinook Yearling | 0 |
| Eastern Brook Trout | 0 |
| Mountain Whitefish | 519 |
| Salmonid total | 10,217 |
|  |  |

Two efficiency trials were conducted with juvenile Chinook (all with hatchery-origin yearlings) at varying cfs (Table 4.). Since RST efficiency and Okanogan River flow have not been correlated in the past and the number of efficiency trials conducted in 2019 was not large enough to show correlation during this year, the WDFW smolt abundance calculator was not employed. Because of the inability to collect sufficient data to confidently estimate juvenile outmigration, abundance estimates were not produced for the 2019 outmigration.

Table 4. Efficiency trials conducted on hatchery-origin Chinook yearlings at the Okanogan rotary screw traps in March and April 2019.

| Trap Date | River Flow @ <br> USGS Malott | Total Chinook <br> Marked and <br> Released | Age Class / <br> Origin | Total Chinook <br> Recaptured | Trap <br> Efficiency |
| :---: | :---: | :---: | :---: | :---: | :---: |
|  |  |  |  |  |  |
| $4 / 2$ | 1,980 | 1,916 | $1+/$ Hatchery | 22 | $1.15 \%$ |
| $4 / 8$ | 2,820 | 2,004 | $1+/$ Hatchery | 3 | $0.15 \%$ |
| Total |  | $\mathbf{3 , 9 2 0}$ |  | $\mathbf{2 5}$ | $\mathbf{0 . 6 5 \%}$ |

## Trap Efficiency and Okanogan CFS

Figure 10. The efficiency trials conducted with hatchery-origin subyearlings are marked in blue.

It should be noted that the efficiency trials using hatchery yearlings from the Omak Pond (Table 4, Figure 10) as a release group is not an ideal proxy for natural-origin subyearling Chinook. In the past, such trials have been used to explore the possibility of using hatcheryorigin yearlings as a surrogate for natural-origin subyearlings, but significant differences in capture efficiency ultimately led to the abandonment of this idea (see 2015 Annual Report). Nevertheless, all trials in 2019 were conducted with hatchery-origin yearlings because of their availability for use and an inability to capture sufficient numbers of natural-origin subyearlings. Twenty-five hatchery-origin yearlings out of 3,920 released were recaptured ( $0.65 \%$ efficiency). The higher trapping efficiencies encountered in previous years for yearling Chinook indicates that the RST may be a useful tool in future years for estimation of yearling out-migrating Chinook. Yearling outmigrants are likely to increase in number once hatchery-origin spring Chinook released into the Okanogan River basin begin to return, and any of their potential progeny out migrate.

Since streamflow did not affect trapping efficiency, efficiency trials were pooled to calculate overall trap efficiency for both natural- and hatchery-origin fish (Table 5). Overall efficiency estimates for natural- and hatchery-origin fish were low as were total catches, leading to a relatively imprecise estimate of total emigration (Table 6).

Table 5. Pooled efficiency trial results for 2.4 m trap configurations. The 1.5 m trap was not installed until 5/1/19 after efficiency trials were conducted; this is subject to flow conditions as well as yearling fish availability and their target release dates.

| Trap | Stock | Mark-Released | Recaptured | Efficiency |
| :---: | :---: | :---: | :---: | :---: |
| 2.4 m Trap | Hatchery Subyearling | N/A | N/A | N/A |
|  | Hatchery Yearling | 3,920 | 25 | $6.5 \%$ |
|  | Hatchery Subyearling | N/A | N/A | N/A |
|  | Hatchery Yearling | N/A | N/A | N/A |

Table 6. Okanogan River Basin. Two efficiency trials were conducted with hatchery-origin yearling Chinook, and efficiency was low and variable. Juvenile abundance could not be reliably estimated in 2019.

| Species | Population Estimate | Lower 95\% <br> Confidence Interval | Upper 95\% <br> Confidence Interval |
| :---: | :---: | :---: | :---: |
| Hatchery-origin <br> Chinook* | N/A | N/A | N/A |
| Natural-origin*** <br> Chinook | N/A | N/A | N/A |

* A total of 731,449 yearling hatchery-origin Chinook were released into the Okanogan River system upriver from the screw trap site in 2019. 210,582 were released from the Riverside acclimation pond from April 15-30; 240,812 were released from the Similkameen hatchery from April 15 - April 30; 280,055 were released from the Omak acclimation pond on April 15-30; and 8,229 hatchery-origin Chinook were released in Canada into the Okanagan River.

## Juvenile Beach Seine and Pit Tagging

In 2019, 26,757 natural-origin juvenile salmonids were collected in over the course of 13 tagging days (Table 7.). Out of the juvenile summer/fall Chinook collected, 26,439 (98\%) subyearling Chinook were PIT tagged and released (Figure 11). Pre- and post-tag mortality was $2.8 \%$ and $2.5 \%$ respectively. Twenty-six shed tags were recovered from the net pens prior to release, these tags were ejected from fish that were later released alive, but without a tag. All recovered tags were removed from the tagging file before upload to PTAGIS. Fish size increased through time (Figure 12), fish catch peaked June 8 through June 14 (Table 7). By late-June, Columbia River temperatures approached $14^{\circ} \mathrm{C}$ and catch began to decline. We suspect that sub-yearling Chinook may have migrated downstream, or to deeper, cooler water making it difficult to collect them via beach seine, as has presumably happened in past years. Fork length for tagged fish ranged from 43-113 mm, with an average of 67.8 mm (SD 9.6 mm ) and a median of 68 mm (Figure 13). Bycatch included hatchery-origin juvenile Chinook, three-spine stickleback, mountain whitefish, smallmouth bass, and sculpin.

Table 7. Summary of juvenile Chinook beach seining effort at Gebber's Landing in 2019. This table excludes Chinook salmon that were captured, PIT tagged, and then recaptured in the beach seine.

| Week start | Gebber's Fish <br> Collected | Gebber's Fish <br> Tagged | Proportion <br> Gishber's <br> Fishged |
| :---: | :---: | :---: | :---: |
| $5 / 28 / 2019$ | 526 | 526 | $100 \%$ |
| $6 / 5 / 2019$ | 9,668 | 8,927 | $92 \%$ |
| $6 / 11 / 2019$ | 10,892 | 9,417 | $86 \%$ |
| $6 / 18 / 2019$ | 6,058 | 4,926 | $81 \%$ |
| $6 / 24 / 2019$ | 3,152 | 2,643 | $84 \%$ |
| Total | $\mathbf{3 0 , 2 9 6}$ | $\mathbf{2 6 , 4 3 9}$ | $\mathbf{8 7 \%}$ |
| Mean | $\mathbf{6 , 0 5 9}$ | $\mathbf{5 , 2 8 8}$ |  |

Figure 11. Total mortality and number of released natural-origin sub-yearling Chinook in 2019. Primary y-axis shows number of juvenile Chinook; secondary y-axis (right hand side) shows water temperature (degrees Celsius (C)).

Figure 12. Size distribution of PIT tagged juvenile Chinook by release date from the beach seine effort in 2019. Boxes encompass the $25^{\text {th }}$ to $75^{\text {th }}$ percentiles of measured fish; the mid-line in the box is the median fish length. FL = fork length in millimeters (mm).

Figure 13. Size distribution of natural origin sub-yearling Chinook tagged during the beach seining effort in 2019.

The Rocky Reach juvenile bypass system detected 3,279 PIT tagged juvenile Chinook from the beach seining effort, which was $12.2 \%$ of total fish tagged and released. One hundred twenty-nine ( $0.6 \%$ ), 280 (1.1\%) and 11 ( $0.5 \%$ ) were detected at the McNary, John Day, and Bonneville Dams respectively. Detections for sub-yearlings occurred primarily from late-June to early-August at all downriver dams (Figure 14). Utilizing the mark-recapture model from DART, the apparent survival rate was 36\% (SE 2.0\%) to Rocky Reach and 53\% (16.0\% SE) to McNary.

Figure 14. Daily distribution of detections of PIT-tagged sub-yearling Chinook at Rocky Reach, McNary, John Day, and Bonneville Dams in 2019. Note differences in scale on the y-axis. The y axes denote the numbers of PIT-tagged fish encountered daily at each of the mainstem project arrays.

Travel time from release to Rocky Reach Dam was the slowest compared to travel time from release to the other lower river dams - on average, fish moved downstream more quickly the further downstream they travelled (Table 8). Larger fish travelled faster to Rocky Reach Dam (Figure 15). This is similar to what was reported in 2011-2013 by Douglas County PUD and observed in previous years by CCT.

Table 8. Mean travel time (d) and rate (km/d) for PIT tagged sub-yearling Chinook released near Gebber's Landing and detected at Columbia River dam PIT arrays.

| Location (River KM) | Rocky Reach (762) |  | McNary (470) |  | John Day (347) |  | Bonneville (235) |  |

## Lower Okanogan Adult Fish Pilot Weir

The Okanogan River (at Malott) discharge was below normal in 2019 and was below $1,000 \mathrm{cfs}$. for the majority of the trapping season. Staff were able to safely enter the river and begin installation on July 15th when discharge was 1,540 cfs. (Figure 16). Discharge continued to drop throughout the season and was at 1,000 cfs. by the time the weir was removed for the season.

Migration of sockeye and summer/fall Chinook is generally affected by a thermal barrier that is caused by warm water temperatures ( $\geq \sim 22^{\circ} \mathrm{C}$ ) in the lower Okanogan River. The thermal barrier is dynamic within and between years, but generally it sets up in mid-July and breaks down in late August. In some years, the Okanogan River will temporarily cool off due to a combination of interrelated weather factors including rainstorms, cool weather, cloud cover or wildfire smoke. This 'break' in the thermal barrier can allow a portion of the fish holding in the Columbia River to enter the Okanogan and migrate up to thermal refuge in the Similkameen River or Lake Osoyoos. In 2019, temperatures were similar to the median daily temperatures from the last 13 years (Figure 17).

Daily mean temperature was above $22.5^{\circ} \mathrm{C}$ from July 1 to August 22. Daily mean temperature dropped below $22.5^{\circ} \mathrm{C}$ on August 22nd and stayed below this mark until August 30th. Mean temperature dropped below the mark again on September 3rd and stayed below it for the rest of the season.

Figure 16. Discharge of the Okanogan River between July 1 and October 31, 2019. This figure was copied directly from the USGS website (http://nwis.waterdata.usgs.gov/wa).

Figure 17. Temperature of the Okanogan River between July 1 and October 31, 2019. This figure was copied directly from the USGS website (http://nwis.waterdata.usgs.gov/wa).

Dissolved Oxygen varied from 6.0 to 9.6 mg . /L; total dissolved solids varied from 130158 ppm . and turbidity varied from 1.0 and 4.5 NTUs (Table 9). The head differential ranged from 2.0-3.0 cm across the weir panels. The maximum water velocity measured was $2.9 \mathrm{ft} / \mathrm{sec}$ (Table 10).

Table 9. Water quality data at or near the lower Okanogan weir in 2019. Temperature and discharge were taken from the USGS gauge at Malott.

Eight dead fish were removed from the weir between August 1 and September 11. All of the mortalities were Chinook. All mortalities were impinged on the upstream side of weir indicating that they had most likely died upstream and floated down onto the weir.

Tower observations showed that most fish were equally distributed across the river, milling in the river right, left, and center sections (looking downstream). Estimates were quite a bit lower than previous season, especially during the month of August when the pickets were lifted. Estimates were highest during the last week of the weir season when mean daily river temperatures dropped below $22.5^{\circ} \mathrm{C}$ and the majority of fish were trapped. Bank observations showed that the number fish observed holding in the lower pool, 0.8 km below the weir, increased about one week after the thermal barrier breakdown in September (Figure 18). Trapping operations were conducted on August 26-27 and September 9-11 when river temperature was $\leq 22.5^{\circ} \mathrm{C}$. The total fish trapped at the weir in 2019 was 159 with $90 \%$ of them being Chinook salmon (Figure 19). Ninety-three percent of the Chinook trapped were released back into the river (Figure 20). No steelhead were trapped in 2019.

Eight natural-origin and two hatchery-origin Chinook were transported to the hatchery and held in the brood stock ponds concurrently with the fish taken for brood stock from the purse seine. Adult Chinook were transported from the weir trap to the hatchery brood truck via a rubber boot. We were unable to assess the pre-spawn mortality of the weir brood because they were mixed with the rest of the integrated brood when they were transported to the hatchery. If we need to assess pre-spawn mortality in future years, we will need to mark these fish before they are transported to the hatchery or before they are mixed with the other brood at the hatchery.

Figure 18. Estimate of Chinook observed from the bank at the lower pool, 0.8 km downstream of the weir. Primary y-axis indicates number of Chinook observed; secondary $y$-axis (right hand side) indicates the mean stream temperature in degrees Celsius (C).

Figure 19. Total number of fish trapped at the Okanogan weir in 2019.

Figure 20. Final destination of Chinook adults captured in the weir trap during trapping operations in 2019.

In 2019, 0.017 (1.7\%) of total spawning escapement was detected in the trap (i.e., weir efficiency) (Table 11). The potential weir effectiveness (if we had been removing all of the HOR encountered) was 0.001 (0.1\%).

Table 11. The number of hatchery and natural origin Chinook Salmon encountered at the lower Okanogan weir in 2019. Weir efficiency and effectiveness were metrics for evaluating the potential for the weir to contribute to the CJHP population management goals in the future.

${ }^{\text {a }}$ Estimates for weir efficiency are adjusted for prespawn mortality and include Chinook adults that are harvested, released, and collected for brood.
${ }^{\mathrm{b}}$ Estimates for weir effectiveness are adjusted for prespawn mortality and include Chinook adults that are harvested or removed for pHOS management.
c Estimates do not include Chinook Zosel Dam counts.
d NOS and HOS estimates determined by 'reach-weighted' pHOS calculations

## Redd Surveys

In 2019, 2,371 summer/fall Chinook redds were counted in the Okanogan and Similkameen rivers using a combination of ground and aerial surveys (Figure 22). The number of redds counted in 2019 was similar to the previous year (2018) - higher than the long-term average, but less than the more recent 5 -year average (Table 12). Consistent with previous years, the majority of Chinook redds were located in reaches S1 (34\%), 06 ( $30 \%$ ), and 05 ( $21 \%$; Table 15). These three reaches accounted for $85 \%$ of the total Chinook spawning in the basin. The overall redd distribution across reaches was similar to previous years with the majority of spawning taking place in the upper Okanogan reaches (O5 and 06) and lower Similkameen (S1) (Figure 22).

Estimated spawning escapement was 5,453 (2,371 redds $\times 2.3$ fish per redd) (Table 14). Since 1989, the summer/fall Chinook spawning escapement within the U.S. portion of the Okanogan River Basin has averaged 5,848 and ranged from 473 to 13,857 (Table 14).

Summer/fall Chinook redds were counted during spawning ground surveys between September 29 - Nov 16 (Table 15). No spawning ground surveys were conducted after November 16.

Table 12. Total number of redds counted in the Okanogan River Basin, 1989-2019 and the averages for the total time series and the most recent 5-year period.

* Spawning escapement was calculated using the "Modified Meekin Method" (i.e., $3.1 \times$ jack multiplier).
Note: All values have been updated from previous reports to account for low sample rates (i.e., carcass recoveries). For any reach with carcass recoveries <5\%, the annual basin composition (i.e., HOS: NOS) was used to determine the number of HOS and NOS.

## Escapement into Canada

Methodological uncertainties have limited our confidence in Chinook escapement estimates into the Canadian portion of the Okanogan basin. Prior to 2018, insights into escapement into Canada had been based primarily on video counts of fish ascending the passageway at Zosel Dam, with the important caveat being that due to the variations in dam operations, there was uncertainty regarding the proportion of fish that are passing within range of the video system, and thus, available for counting. Additionally, fish fallback and re-ascension is known to occur (as indicated by limited PIT tag data), though the frequency of occurrence is poorly understood. With these uncertainties in mind, we present Canadian escapement information for years prior to 2018 (Table 18). No video count data exists for Chinook in 2018 and 2019. Average Chinook passage at Zosel Dam for years 2010 thru 2017 has been 1,315 , with a minimum of 263 (2010) and a maximum of 2,276 (2013).

Table 16. Chinook escapement to Canada as estimated by Zosel Dam counts and Okanogan Nation Alliance area-under-the-curve (AUC) methods.

| Year | Zosel Dam <br> Video Count | Zosel Dam \% <br> Hatchery | ONA AUC <br> Spawner <br> Estimate | ONA AUC \% <br> Hatchery |

| 2019 | No Data | No Data | 15 | $18 \%$ |
| Average | $\mathbf{9 4 1}$ | $\mathbf{1 9 \%}$ | 39 | $\mathbf{1 0 \%}$ |

${ }^{a}$ AUC spawner estimates is based on the number of carcasses sampled so this is the minimum estimate. ${ }^{\text {b }} 2014$ data were adjusted for fallback/re ascension, down camera time, and differentiation of spring Chinook from summer/fall Chinook.

More recently, Okanagan Nation Alliance (ONA) has provided information on escapement estimates in Canada based on live counts of summer Chinook adjusted by the residency estimate for the area-under-the-curve (AUC). Using AUC estimation methods, the largest spawner estimate occurred in 2015 with 61 spawners (Table 16). In 2019, 0NA estimated 15 Chinook on Canadian spawning grounds.

## Carcass Surveys

In 2019, 467 carcasses were recovered on the spawning grounds, including 226 natural-origin and 241 hatchery-origin ${ }^{7}$. An additional 6 carcasses were recovered during pre-spawn surveys ( 3 ad-clipped, 3 ad-present). The spawning ground carcass recovery rate was $8.6 \%$ of the total spawning escapement. Similar to previous years, the majority of carcasses ( $n=379$; 81\%) were collected from reaches 05, 06 and S1 (Figure 23, also see

[^6]Appendix C). Regarding the distribution of carcasses throughout the basin, the proportions of natural-origin carcasses recovered in 2019 were significantly lower in reach S1, and higher in reach 03, compared to the average of the 10 years preceding Chief Joseph Hatchery (Figure 23, panel A). The proportions of hatchery-origin carcasses recovered in 2019 were significantly higher in reaches 03 and 06, and lower in reaches S1 and S2 compared to the average of the 10 years preceding Chief Joseph Hatchery (Figure 23, panel B).

Figure 23. Distribution of (A) natural-origin and (B) hatchery-origin summer/fall Chinook carcasses recovered in the Okanogan (reaches 01-06) and Similkameen (reaches S1-S2) Rivers in 2019 compared to the average of the 10 years preceding Chief Joseph Hatchery (2006-2015). Error bars represent standard deviation (SD).

In the Okanogan basin, just 6 of the 283 sampled female carcasses were estimated to have retained all their eggs. Therefore, pre-spawn mortality, (for fish that survived to the spawn period) was estimated to be $0.82 \%$ for natural-origin females and $2.48 \%$ for hatchery-origin females (Table 17). Overall egg retention of all fish sampled (including fish that had expelled a portion of their eggs) was $1.97 \%$.

Table 17. Egg retention and pre-spawn mortality of sampled summer/fall Chinook carcasses in the Okanogan Basin.

${ }^{\text {a Assuming fecundity of } 5,000 \text { eggs per female, egg retention rate is calculated as: (\# eggs estimated remaining in sampled }}$ female carcasses) / (\# female carcasses sampled * 5,000 eggs each)
${ }^{\mathrm{b}}$ A pre-spawn mortality is determined when a female retains the assumed 5,000 eggs on the spawning grounds.

## PHOS AND PNI

There was an increase in the proportion of hatchery-origin spawners ( pHOS ) across all reaches in 2019 compared to the 10 years preceding Chief Joseph Hatchery (Figure 24). However, few carcasses were recovered in reaches 01, 02, and 04( $n<5 \%$ ) of estimated spawners) therefore, no comparisons could be made as to the composition of spawners in
these reaches. Combined, these three omitted reaches comprised only $10.9 \%$ of the spawning in the basin in 2019. Basin means (average pHOS) were used for these reaches in all subsequent analyses. Hatchery-origin spawners comprised 52\% of the spawn escapement estimate in the U.S. portion of the Okanogan, which was the highest pHOS observed since 2011 (also 0.52) (Table 18). After corrections for hatchery fish effectiveness assumptions ( 0.80 relative reproductive success rate for hatchery-origin spawners) the effective pHOS for 2019 was 0.47 , which was well above the five-year average (0.29) (Table 19). Despite this single year increase, the five-year average is currently meeting the biological objective for $\mathrm{pHOS}(<0.3)$ (Figure 25).

The proportion of natural-origin broodstock (pNOB) in 2019 was 0.63 and the pNOB for Okanogan origin fish was 0.56 (Table 19). The resulting PNI for 2019 was 0.57 , with a 5-year average PNI of 0.78 . Despite the undesirable decrease in PNI over the last two years (2018 and 2019), the 5-year average is still meeting the Biological Objective ( $>0.67$ ) (Figure 26).

Figure 24. Okanogan (01-06) and Similkameen (S1-S2) river summer/fall Chinook pHOS (unadjusted for RSS) by reach. Red bars represent the average of the 10 years preceding Chief Joseph Hatchery (2006-2015), green bars represent the average of the years since Chief Joseph Hatchery operation (2016-2019), and blue bars represent the current year (2019). Reaches with <5\% carcasses recoveries were omitted. Error bars represent standard deviation.

Figure 26. Annual and 5-year average proportionate natural influence (PNI) in the Okanogan basin from 1998 to 2019.

## Age Structure

Attempts were made to age all carcasses recovered on the spawning grounds, either by microscopy of scale annuli for natural-origin fish or by extracting and reading coded wire tag information for hatchery-origin fish. Historically, most natural-origin summer Chinook outmigrate as sub-yearlings, while the majority of hatchery-origin releases in the Okanogan River basin have been released as yearlings. To account for this difference, the number of winters a fish spent in the marine environment - salt age - is the format of reported data.

In 2019, male natural-origin spawners were comprised predominantly 2-and 3year salt age fish, which is similar to previous years (Figure 28-a). Natural-origin female spawner age structures were skewed towards 2-year salt age fish compared to previous years (Figure 27-b). With 108 natural-origin female Chinook collected on the spawning grounds in 2019, none were determined to be 4 -year salt age. Hatchery-origin males were comprised by 1- and 2-year salt age fish. No 3-year hatchery-origin males were recovered. Hatchery-origin females were comprised of 2-and 3-year fish, with no 4-year fish recovered.

## d) Hatchery-origin Female Age Structure

Figure 27. The salt ages of carcasses collected on the spawning grounds of the Okanogan and Similkameen rivers in 2019 along with 10-year averages (2010-2019) for a) Naturalorigin males; b) Natural-origin females; c) Hatchery-origin males; and d) Hatchery-origin females.

## HATCHERY-ORIGIN STRAY RATES

Strays to the Okanogan-The majority (68\%) of hatchery-origin spawners recovered on the spawning grounds in 2019 were from Similkameen (44\%) and Okanogan acclimated (24\%) releases (Table 20). Chief Joseph Hatchery segregated Chinook comprised $34 \%$ of the HOS on the Okanogan spawning grounds. Strays into basin consisted
of individuals from Methow River, Entiat River, Chelan River, mainstem Columbia River, and Snake River releases. Stray hatchery fish from outside the Okanogan basin comprised 21.4\% of the total (HOS+NOS) Okanogan spawner composition (i.e., stray pHOS) (Table 21). This was far above the recent (2006-2019) average of $4.01 \%$ and also above the biological target of $<5 \%$. Note that this includes those fish released from the Chief Joseph Hatchery segregated program.

Strays outside the Okanogan - With the caveat that data are likely to continue to be updated in future reports as more data becomes available through the RMIS database, the most recent brood year that could be fully assessed (through age 5) for stray rate of Okanogan fish to spawning areas outside the Okanogan was 2014. The 2014 brood year had a stray rate of $1.9 \%$ (includes straying to out of basin spawning grounds and hatcheries), which was slightly above the long term (1989-2014; 1.3\%) and recent fiveyear (2009-2013; 1.5\%) averages (Table 22). RMIS queries revealed an estimate of 16 Okanogan hatchery-origin Chinook recovered on spawning grounds in non-target spawning areas in 2019 (Table 22). Okanogan basin hatchery program strays comprised $1.35 \%$ to Chelan spawner composition in 2019 (Table 23). 5-year averages to Wenatchee, Methow, Chelan, and Entiat basins are all below 1\%.

Table 20. Estimated number (and percent of annual total) of hatchery-origin spawners from different release basins recovered on the Okanogan/Similkameen spawning grounds, based on CWT recoveries and expansions, for return years 20062019.

${ }^{\text {a }}$ Includes releases from Bonaparte Pond. Three spring Chinook recovered in 2008 from an Omak Creek release were excluded from analysis.
${ }^{\mathrm{b}}$ Includes releases from Similkameen Pond
${ }^{c}$ Includes releases from Carlton Acclimation Pond
${ }^{d}$ Includes releases from Dryden Pond and Eastbank Hatchery
${ }^{e}$ Includes releases from Entiat NFH
${ }^{\mathrm{f}}$ Includes releases from Chelan PUD Hatchery, Chelan River NFH, and Chelan Hatchery
g Includes releases of summer Chinook from Wells Hatchery, Turtle Rock Hatchery, and Grant County PUD Hatchery
${ }^{\text {h }}$ Includes releases of fall Chinook from Hanford Reach
${ }^{\mathrm{i}}$ Includes Releases from NPT Hatchery
j Includes releases from Marion Yakama Tribal, Cle Elum Hatchery, Irrigon, and Prosser Hatchery

Table 22. Number and percent (\%) of hatchery-origin Okanogan summer/fall Chinook that were recovered at target spawning areas or were captured at en route hatcheries (Wells and Chief Joseph Hatchery), and number and percent that strayed to non-target spawning areas and non-target hatcheries, brood years 1989-2014. As fish continue to return through time and the RMIS database is continually updated, reported data from recent brood years may change.

| Brood Year | Homing |  |  |  | Straying |  |  |  |

## Homing Fidelity

The 141 coded-wire tags recovered during spawning grounds surveys in fall of 2019 expanded to 403 and 1,250 spawners originated from Omak Pond and Similkameen Pond acclimation sites, respectively. The majority (90\%) of the spawners originating from the Omak Pond acclimation site spawned in the Okanogan River (Table 24). Those fish tended to spawn in habitat upstream of the Omak Pond site, with the majority (46\%) in reach 05. No Omak Pond or Similkameen pond CWT's were recovered below reach 03 (Figure 28). Forty-one of the 403 fish (10\%) that were acclimated at Omak Pond were recovered in the Similkameen River (reach S1). Most fish acclimated at Similkameen Pond spawned in the Similkameen River (51\%). Of the Similkameen-origin fish that spawned in the Okanogan River, most used reaches 05 and 06 (40\% combined; Figure 28). However, some of the CWT recoveries in reach 05 could have been fish that spawned upstream in S1 and swam or drifted downstream after spawning. Reach S1, the location of the Similkameen acclimation site in the Similkameen River, accounted for almost half of the estimated spawning by Similkameen Pond fish (48\%) (Table 24).

Table 24. Spawning distribution by river, for fish acclimated at Omak Pond and Similkameen Pond acclimation sites for 2018 and 2019.

| $\mathbf{2 0 1 8}$ | Acclimation site (origin) |  |
| :---: | :---: | :---: |
| Spawning location | Omak <br> Pond | Similkameen Pond |
| Okanogan River | $92 \%$ | $60 \%$ |
| Similkameen River | $8 \%$ | $40 \%$ |

| $\mathbf{2 0 1 9}$ | Acclimation site (origin) |  |
| :---: | :---: | :---: |
| Spawning location | Omak <br> Pond | Similkameen Pond |
| Okanogan River | $90 \%$ | $49 \%$ |
| Similkameen River | $10 \%$ | $51 \%$ |

Figure 28. 2019 spatial distribution of CJHP integrated program summer/fall Chinook spawners originally reared at the Similkameen Pond and Omak Pond acclimation sites and CJHP segregated program strays to Okanogan spawning grounds.

## Smolt Survival and Travel Time

Apparent survival of yearlings to RRJ in 2019 was $67 \%$ (SE 4\%) for the segregated program released from CJH, $69 \%$ (SE 3\%) for integrated fish released from Omak Pond and $63 \%$ (SE 3\%) for Similkameen (Table 25). Apparent survival of yearlings to MCN was $45 \%$ (SE 10\%) for the segregated program released from CJH, $50 \%$ (SE 8\%) for the integrated fish released from Omak Pond and 53\% (SE 10\%) for Similkameen (Table 25). The segregated yearling program from CJH had lower survival than the five-year mean, whereas the integrated program at Omak Pond had higher survival than the five year mean to RRJ and the same as the five year mean to MCN (Table 26).

There was not a subyearling program at the CJH or Omak Pond in 2019. Wild subyearlings had a survival to RRJ of $36 \%$ (SE 2\%) and $18 \%$ (SE 5\%) to MCN (Error! Reference source not found.). The survival of wild summer Chinook from release to RRJ and MCN was very similar to the five-year mean (Table 26).

Table 25. Apparent survival estimates for PIT tagged summer/fall Chinook released in 2019 from Chief Joseph Hatchery (CJH), Omak Pond and other nearby hatcheries.

Releases of yearling Summer Chinook smolts began on April 15, 2019. Of the 4,987 PIT tagged fish released from Omak Pond (rkm 52), only 44 were detected at the Lower Okanogan PIT detection array. Fifty percent passed OKL within eight days and $90 \%$ passed within 21 days. Only four fish released from Similkameen Pond were detected at OKL, therefore the sample size was too small to calculate passage timing. The mean travel time of summer Chinook released from CJH facilities to RRJ in 2019 varied from 23 days ( $6.4 \mathrm{~km} /$ day) for yearlings released from Omak Pond to 32 days ( $3.6 \mathrm{~km} /$ day) for yearlings released from CJH (Table 27). Travel times to RRJ, MCN and BON were noticeably longer for all programs in 2019 compared to the fiveyear means (Table 28, Table 29). The majority of yearling Summer Chinook from CJH and Omak Pond arrived at RRJ from early May to mid-June, with $90 \%$ passage dates of June 15 and May 30, respectively (Figure 29). The programs appeared to be successfully releasing actively migrating smolts and the migration speed increased substantially in reaches downstream of Rocky Reach Dam for all release groups (Table 27).

Table 27. Travel time (days), migration speed (km/day) and the number of days to $90 \%$ passage for summer/fall Chinook release groups in 2019.

Figure 29. Arrival timing at Rocky Reach Juvenile bypass (RRJ) of PIT tagged Summer Chinook released from the Chief Joseph Hatchery and Omak Pond in 2019.

## Smolt-to-Adult Return (SAR)

SAR was estimated using two methods, PIT tags and coded-wire tags.

PIT based estimate of SAR—The most recent brood year that could be fully assessed with PIT tags (through age 5) for SAR was 2014. For CJH segregated Summer Chinook from brood year 2014 (outmigration year 2016), 64 adult fish (age 4\&5) returned to Bonneville Dam with a PIT tag, resulting in SAR estimates of $1.3 \%$ before harvest and $1.7 \%$ with harvested fish added back in (Table 30). For brood year 2014, the SAR back to Wells Dam was $0.8 \%$ before harvest and $2.0 \%$ with harvested fish added back in (Table 30).

For the brood year 2014 integrated yearling program released from Omak Pond, 28 adult fish (age 4-5) returned to Bonneville Dam with a PIT tag, resulting in SAR estimates of $0.7 \%$ before harvest and $0.9 \%$ with harvested fish added back in (Table 30). For brood year 2014, the SAR back to Wells Dam was $0.4 \%$ before harvest and $0.7 \%$ with harvested fish added back in (Table 30).

The subyearling program showed considerably worse SARs, with no adult PIT tagged fish returning from the segregated program thus far, resulting in an SAR estimate of $0 \%$. For the brood year 2014 integrated sub yearling program at Omak Pond, three age 4 fish returned in 2018 resulting in a raw SAR of $0.06 \%$ and a harvest corrected SAR of 0.09\% (Table 31).

Table 30. Estimate of the smolt to adult return rate (SAR) for yearling Summer Chinook from Chief Joseph Hatchery and Omak Pond. Adult return data were available through 2019, therefore the most recent brood year that could be assessed through age 5 was 2014.

CWT-based estimate of SAR—Based on expanded CWTs, the 2011 brood year had a SAR of $3.1 \%$, which was above the long-term and 5-year averages. However, this number may change as more adult captures from BY 2012 are uploaded to the RMIS database, and this table changes in the coming years to reflect those data (Table 32).

Table 32. Smolt-to-adult return rate (SARs) for Okanogan/Similkameen summer/fall Chinook, brood years 1989-2012.

## DISCUSSION

## Rotary Screw Traps (RST)

In past years, primarily attributable to low capture efficiency, the data produced by the RST has proved insufficient to provide for estimation of juvenile production in the previous brood year

The pooled trap efficiency of approximately $<1 \%$ is much lower than in previous years (Rayton and Arterburn 2008, Johnson and Rayton 2007;https://static1.squarespace.com/static/56f45574d51cd42551248613/t/57c06a21e 58c62290279a3d7/1472227873603/2006 Screw Trap Report Final.pdf; https://static1.squarespace.com/static/56f45574d51cd42551248613/t/57c06a12e58c62 290279a376/1472227860447/2007RstReportFinal.pdf), and remains insufficient to precisely estimate juvenile production for the basin. Additionally, the 95\% confidence interval for hatchery-origin population was far too broad to provide information useful in making informed decisions. This indicates that, due to the difficulties in accurately estimating trap efficiency and juvenile production, the results of screw trapping activities in 2019 are to provide an accurate estimate of juvenile production.

NOAA Fisheries suggested a goal for precision of juvenile outmigration monitoring was to achieve a coefficient of variation (CV) of $15 \%$ or less (Crawford and Rumsey 2009). It is not clear that this level of precision is attainable in any large river system using conventional sampling methods such as a rotary screw trap (see Scofield and Griffith, 2014). Still, improving trap efficiency and narrowing juvenile emigration estimates remains the goal of CJHP such that informed management decisions can be made. Environmental factors such as river discharge, configuration, and trap size influenced the efficiencies of these trials. In order to mitigate these confounding variables, we will continue to attempt to conduct more frequent efficiency trials with large release groups (n $\geq 1000$ ).

Again, no relationship between Okanogan River flow and trapping efficiency was observed, and the flow regression model used by other agencies in other river systems (Murdoch et al. 2012) was not applied to estimate outmigration. The CJHP will continue to assess methods to improve capture techniques to increase the precision of juvenile production estimates.

Historically differing efficiency rates for trials involving yearling and sub-yearling fish indicate that using hatchery releases of yearling fish as a surrogate to measure natural production would be inappropriate. However, in future years when wild spring Chinook yearlings are present and out-migrating in measurable quantities, this possibility could be
reexamined. This should be especially relevant once integrated, §10(j) spring Chinook, first released from the Riverside Acclimation Pond in April 2015, begin to return, and spawn.

Finally, Pacific lamprey (Entosphenus tridentatus) were captured in the RST in both 2006 and 2007 but were not observed from 2008 to 2019. The status of this fish, an important cultural and ecological resource in the Okanogan River Basin is not examined in this report, but its disappearance from the RST is noteworthy.

## Juvenile Beach Seine

The CJHP took over the beach seining effort in 2014, adopting methods used by Douglas County PUD and Biomark in 2011-2013. Given the low catch rate of taggable summer/fall Chinook from the RST, beach seining appeared to be a more reliable opportunity to capture large numbers of taggable summer/fall Chinook juveniles. Again in 2018, PIT tags deployed at the beach seine far outnumbered tags deployed at the RST.

Mortality related to capture, handling and tagging was similar to what it has been in previous years. Maintaining water temperatures below $18{ }^{\circ} \mathrm{C}$, reducing MS-222 concentrations in the anaesthetizing solution, and further limiting handling time during tagging and capture likely contributed to this low pre- and post-tagging mortality. The hope for future years is to continue to reduce overall mortality associated with our PIT tagging efforts.

Fish size increased through the tagging period, but the number of fish captured and CPUE began to decrease in late June, which is later than what had been observed previous to that. Interestingly, dates of detection at downstream PIT arrays occurred about the same as they had in 2016 and 2017.

We do not have absolute certainty regarding natal stream for any of the juvenile Chinook fitted with a PIT tag, but assume the vast majority, especially of fish captured at the Gebber's location, are of Okanogan origin. However, juvenile summer Chinook in the Wells Pool originate from the Methow and Columbia Rivers as well. Therefore, future analyses of returning adults must recognize that some fish may not be destined for the Okanogan. Results from the stable isotope analysis conducted in 2018 indicated that most fish collected from the Gebber's location are of Okanogan River origin (See 2018 Annual Report, Appendix E).

## Lower Okanogan Adult Fish Pilot Weir

Discharge conditions on the Okanogan River in 2019 were quite a bit lower than those in previous years, allowing installation and operation of the weir in mid- July, which was a month earlier than 2018. Temperatures on the Okanogan River were fairly normal, compared to the 13-year median. They were not a factor for trapping operations once they began on August 26th. Tower observations were relatively low for the majority of the season outside of the last week in July and second week of September, the final week of operation. Bank fish observations were pretty steady throughout July and August and increased after the water temperature stayed below $22.5^{\circ} \mathrm{C}$ in early September. In September, fish observations 0.8 km . below the weir, at the lower pool, were similar than observations at the weir. However, this was not the case for August, when bank observations were much higher than the tower observations below the weir. When river temperature was lower and gage height was less than 4 feet, Chinook were more likely to mill in deeper pools, but in previous years tower observations were much higher in September. It's reasonable that there were more fish milling in the lower pool than there were milling around the weir in August. In August pickets were up on the weir panels due to a high density of algae in the river. The algae was creating a dense blanket across the weir panels and became too difficult for crew to maintain the weir without creating a head differential across the panels that was within the project's operating criteria. Continued monitoring of Chinook passage through the weir with respect to temperatures should continue in order to better refine weir operations and future expectations for weir effectiveness.

The number of Chinook handled at the weir ( $\mathrm{n}=143$ ) was more than in 2018 ( $\mathrm{n}=$ 48). Configuration of the weir was similar to that in 2018 with the trap installed downstream, on the edge of the thalweg, and below the deep pool. The fish entrance chute was added to the trap gate again to test whether it would increase entrainment to the trap box. We evaluated the water conditions as it relates to discharge and stage height and think that we should continue to install the trap at the same location as 2019 to continue testing it with the chute.

None of the water quality parameters monitored were at a level that would cause concern regarding an environmental effect of the weir on water quality. However, there are other water quality parameters that were not measured (i.e., pH , phosphorous, or nitrogen) that may have provided some insight to the algae issue. The number (8) of dead fish at the weir was the lowest it has ever been, and that can be a result from a lower potential to collect carcass washdowns in 2019. If the weir pickets were down more there likely would have been more prespawn mortalities collected. There were no fish impinged between pickets (head upstream) in 2019. In an attempt to assess immediate indirect mortality, we marked and released adult natural-origin Chinook at the weir trap in 2016 and 2017. Because of the concern for over handling fish in a year with fewer returns and a lack of carcass recoveries on the spawning grounds, we did not conduct a mark-recapture study in 2019. We do not anticipate additional studies in the near future.

There were fifteen sockeye trapped in 2019. It is likely that more sockeye moved through the weir panels when pickets were up. When pickets were down and the trap was operating, there were no observations of jack or small adult Chinook escaping through the 2 " weir panels that were intended to allow sockeye passage. We will continue to use the 2 -inch weir panels again next year to increase the efficiency of Chinook trapping without causing too many sockeye to also use the trap.

There was no way to know exactly how many fish escaped past the weir before it was installed or how many fish swam through, around or jumped over the sealing aprons after it was installed. The potential weir effectiveness measure of $0.1 \%$ was very low. The thermal barrier did not set up until late July, which was shortly after the weir was fully functional so it's likely that more fish passed the weir before it was installed. The barrier broke down in late August. Fortunately, this did not affect fish management objectives in 2019 because with a lower adult return, CCT decided to only collect broodstock at the weir and release all others, regardless of origin, back to the river to escape to the spawning grounds. In the future, with larger returns of hatchery fish due to CJH releases we anticipate a much higher pHOS at the weir resulting in higher weir effectiveness. Continuing these evaluations in future years will be critical to determining the long-term viability of the weir as a fish management tool for summer/fall Chinook.

The brood stock collection protocol at the weir was to get $15 \%(n=84)$ of the integrated program). By the time the weir trap was operational the protocol changed to collect up to 10 natural-origin and/or hatchery-origin adults. The weir met its brood stock goal, collecting 8 natural-origin and 2 hatchery-origin fish in late August and midSeptember, after the post thermal barrier breakdown period.

In 2019 CCT F\&W staff were able to safely and successfully deploy, operate, and monitor the weir and add to the multi-year evaluation of the weir as a fish management tool for the CJH program. Although the program experienced a limited trapping season and
lower than expected adult summer/fall Chinook returns, the weir was successful at collecting some brood stock for the hatchery's integrated program. The weir's importance to the Okanogan summer/fall Chinook population should increase in the coming years with larger hatchery returns resulting from the increased production at CJH. Experiencing a broad range of environmental conditions spanning the extremely high summer flows of 2012 to the very low and warm flows in 2015 or high algal densities in 2019 is important for understanding the range of challenges and resulting weir effectiveness that can be expected through time.

## Redd Surveys

Summer/fall Chinook spawning consisted of 2,371 redds in 2019, which was above the long-term average ( 2,216 for 1989-2019) but below the more recent 5-year average of 3,451 . Redd counts were below average across most reaches in the Okanogan and Similkameen rivers ( $01,04,05,06, S 1$, and S2) but actually increased compared to the average in the lower Okanogan River (reaches 02, 03) (Table 15).

The redd count in reach 06 - which most years, supports the largest proportion of natural-origin spawners - was the second lowest count on record, which dates back to 2006. Likewise, reach S1 in the Similkameen River - which generally supports the highest proportion of hatchery-origin spawners has its third lowest redd count going back to 2006.These two adjacent reaches, along with reach 05 (which also saw a slight reduction in the number of redd) still provide the primary spawning habitat for summer/fall Chinook in the Okanogan/Similkameen basin, comprising 76\% of the total spawning in 2019. One objective of the CJHP is to increase the spatial distribution of spawning into the lower reaches of the Okanogan. Historically, a low proportion of the spawning activity has occurred in these reaches (01-04), likely due to lower quality spawning habitat (increased fine substrate, reduced gradient, increased pool habitat). The 2019 redd counts showed an increase in the proportion of redds in reaches 01,02 , and 03 - continuing the trend from 2017 and 2018. Although the changes are modest, they represent progress towards a goal that will likely take a long time to fully achieve. CJHP Chinook reared at the Omak Pond acclimation site (located around the break between reach 03 and 04) may be contributing to increased spawning in lower reaches through natal homing. Continued monitoring of redd and carcass distribution will be critical to evaluate this metric.

Chinook spawning in the Okanogan generally begins as water temperatures drop below $15^{\circ} \mathrm{C}$. Conditions in 2019 were characterized by reduced discharge and increased stream temperatures going into the spawning period (Figure 2). However, despite these challenging holding conditions for Chinook, conditions improved (discharge increased and stream temperatures cooled to below average) at approximately the beginning of the spawning period (October). The greatest single week count of redds occurred between October 6 to October 12. Spawning lower in the Okanogan Basin (reaches 01, 02, and 03)
appears to have peaked slightly later, with peak counts occurring the week of October 2026. Few redds were recorded in November, as most spawning was complete by then (Table 19). Although aerial surveys contribute a relatively small portion of the observed redds compared to ground or float surveys, they remain an important tool for documenting spawning, or lack of, in areas not accessible by ground crews.

As in previous years, the fish per redd expansion is based on the sex ratio of fish passing Wells Dam. This method has been used since at least 1998 (Hillman et al. 2014) and is still being applied to both the Methow and Okanogan Chinook populations. However, there is uncertainty that the combined sex ratio of hatchery- and natural-origin summer/fall Chinook at Wells Dam is representative of the Okanogan population because it also includes Methow returns, mainstem released hatchery-origin Chinook, as well as roaming downstream hatchery- and natural-origin Chinook. If the Okanogan has a different ratio of precocial males (jacks) than that of the Wells count, then the Okanogan abundance estimate could be biased. We suggest exploring other approaches to estimating the number of fish per redd in the Okanogan and Similkameen Rivers. Until then, the annual spawning escapement will continue to be calculated using the sex ratio of fish at Wells Dam.

## Escapement into Canada

Escapement of summer/fall Chinook into Canada had been largely overlooked until recent years, aided by video counts of Chinook passing over Zosel Dam. Spawning escapement to Canada has still been difficult to assess, as the video counts represent run escapement and the relationship between run escapement and spawn escapement is not clear. In 2018, video monitoring at Zosel Dam was discontinued, so we are now further limited in our ability to assess Chinook spawning escapement into Canada. In recent years, a substantial number of Chinook have been counted passing Zosel Dam, ranging from a low of 737 to a high of 2275 between 2013 and 2017 (Table 20), so there is the potential for Canada-bound Chinook to have a significant contribution to the trans-boundary Okanogan summer/fall Chinook population. No formal Chinook spawning grounds surveys are currently being conducted in Canada, but surveys for Sockeye (O. nerka) occur annually. Biologists in Canada have observed small numbers (i.e., substantially fewer than the Zosel Dam video counts) of Chinook spawners building redds in the Canadian portion of the Okanogan River (R. Bussanich, ONA, pers. comm., 2014). There is a clear need for increased collaboration between agencies to better monitor and manage this trans boundary population. Researchers and managers for CCT and ONA have begun to discuss research and monitoring needs as well as potential strategies for accomplishing monitoring goals.

Research \& monitoring needs may include:

1. Organization of protocols and methods for formal Chinook spawning grounds
surveys in Canada
2. Increased PIT array systems to better assess PIT-tagged fish passage into Canada

## Carcass Surveys

Spawning ground monitoring efforts resulted in an 8.6\% carcass recovery rate, which was well below the target carcass recovery rate of $20 \%$. However, it is unclear if $20 \%$ is necessary to obtain reliable biological-data or what the implications of reduced sampling rates may be. Zhou (2002) reported fish length as a significant factor in carcass recovery probability, with larger fish recovered at a higher rate than smaller fish. This is especially important as it relates to precocious males, or jacks, which are expected to occur with higher frequencies in hatchery-origin Chinook. Failing to assess and correct for biases and population discrepancies could lead to potential underestimation of hatchery-origin Chinook survival (resulting in inflated hatchery production) or over-estimation of wildorigin Chinook survival (masking potentially negative effects of the hatchery program) (Murdoch et al. 2010). We are considering methods (e.g., mark-recapture) to assess and quantify potential size bias in our carcass recovery efforts.

Spawning grounds surveys beginning in mid-August and lasting through November 16 revealed very few carcasses attributable to pre-spawn mortality, or PSM. Of the 283 female Chinook carcasses recovered, only $1.77 \%$ were determined to have expired prespawn. Also, few female carcasses had retained a significant portion of their eggs, with an egg retention rate of just $1.97 \%$. In other words, it appears that if a significant pre-spawn mortality event takes place, it occurs prior to the spawning period in October, or even late September, as the carcasses we recover on the spawning grounds are nearly all void of eggs. Given the challenging thermal conditions encountered by Chinook in the Okanogan River, it is likely that the majority of PSM occurs earlier in the season while water temperatures are higher and are a greater risk to fish attempting to travel to or hold near the spawning grounds. If this were true, the current design of our redd/carcass surveys would provide an underrepresentation of actual PSM. Therefore, egg retention and prespawn mortality results should be interpreted cautiously. One thing of note is that carcasses that are collected during spring Chinook spawning ground surveys in August and September are assessed via coded wire tag recovery to determine spring or summer run. During the 2019 surveys, 3 summer Chinook pre-spawn mortality carcasses were collected, one each in Loup Loup Creek, Aeneas Creek, and Bonaparte Creek. The carcasses of fish that died prior to the onset of spawning and before sampling began may have been carried downstream of recovery floats, consumed by scavengers, or covered with sediment, making them unavailable for sampling or harder to detect and collect. This could result in an underestimation of pre-spawn mortality. The protocol assumes that each female may contain up to 5,000 eggs and were only considered pre-spawn mortality if they retained >

4500 eggs. A static fecundity assumption may not be the best approach because younger and smaller females will likely have fewer eggs. We expanded the assessment to include an evaluation of fish that retained greater than 1,000 eggs as an attempt to capture some of the variability in fecundity and situations where fish died before depositing a biologically important portion of their eggs. However, even when considering any female that retained $\geq 1000$ eggs, the estimated PSM remained unchanged. We suggest continued review and modification of the egg retention estimation methods/protocol in the future.

## PHOS AND PNI

The biological target for CJHP is to maintain a 5-year average pHOS <0.3. 2015 was the first year since the CJHP began monitoring the population that the 5-year average (0.30) met this objective. 2019 pHOS (0.47) was above the biological target, however, the 5 -year average remained within the parameter at 0.25 . The program failed to meet the biological target for PNI ( $>0.67$ ) in 2018 and again in 2019 ( 0.57 ). However, the 5 -year mean PNI ( 0.75 ) remains above objective. The increased hatchery-origin contribution on the spawning grounds is a result of CJH segregated fish, which stray at an appreciable level to the Okanogan and Similkameen rivers. In the future, we suggest that continued aggressive removal of hatchery-origin fish through selective fisheries and adult management at the weir and hatchery ladder given the uncertainty regarding the adequacy of the objectives to meet long-term population conservation goals. Exceeding the targets whenever possible also provides a buffer for years when goals may not be achieved due to low run size or challenging environmental conditions.

## Origin of Hatchery Spawners

Hatchery-origin Chinook recovered on the spawning grounds in the Okanogan Basin were predominantly (68\%) from Okanogan and Similkameen acclimated, CJH Integrated Program releases. CJH Segregated fish made up 36\% of the hatchery-origin spawners, and $19 \%$ of the total spawning escapement. Stray hatchery-origin fish originating from outside the Okanogan made up $2.7 \%$ of the total estimated spawners, which was less than the goal of $5 \%$, although if we include the CJH segregated spawners, the stray rate increases to 21.7\%. Okanogan Basin hatchery-origin fish strayed to other areas at a low rate ( $0.9 \%$ to non-target basins and 1.0\% to non-target hatcheries, based on RMIS queries of the 2014 BY) and were a small percentage of the spawner composition in other Upper Columbia tributaries in 2019 (less than 2\% in any stray basin). Fish released within the Okanogan Basin have consistently homed to their natal stream, and 2019 was not an exception. One of the goals of the CJHP is to redistribute Chinook spawners to the middle and lower portion of the Okanogan River instead of inundating the already saturated Similkameen River with additional spawners. Juvenile Chinook releases from the Omak Pond acclimation site are primarily spawning in the Okanogan River (92\% in 2018 and 90\% in 2019) instead
of the Similkameen River. Specifically, the Omak Pond-reared Chinook have spawned almost exclusively in the lower ( 03 reach) and middle ( 05 reach) sections of the Okanogan River.

## Smolt Survival and Travel Time

The survival results for each release group provide a useful index of annual survival for comparison between release groups and, in the future, between years. Statistical tests were not conducted to determine if observed differences were statistically valid because we believe this should be done with a multi-year data set and the few total years for which we currently have results. Targets for post release survival have not been established, but it was encouraging to see that the 2019 estimates of CJH programs were similar to nearby programs and the five-year mean, despite large increases in travel time to Rocky Reach and McNary dams. In the future, with more years of smolt migration data, the program should develop a statistical framework for evaluating smolt-to-smolt survival and establish targets that could be used to help adaptively manage the release strategies, if it is determined that survival or travel time are not adequate to meet program goals. Similar to previous years, the hatchery fish migrated out of the system relatively quickly in 2019 , with $90 \%$ passage at OKL within 21 days and only two detections after May 19. This assessment suggests that the program was successful at releasing actively migrating smolts. This analysis did not attempt to account for detection probability at OKL and sample size was relatively small for the Omak Pond release ( $n=44$ ) and extremely small for the Similkameen release ( $n=4$ ). It is likely that the detection rate was different throughout the time period when smolts were detected. However, detection rates at large river arrays generally increase with decreased flow, so late arriving fish would have a better chance of being detected at OKL than fish outmigrating during high flows from April to June. Therefore, it is not likely that a meaningful number of late migrating smolts or residual hatchery fish would have crossed OKL when compared to what was detected during peak migration. Although the OKL PIT detection site is 25 km from the confluence with the Columbia River, it is very close ( $\sim 2 \mathrm{~km}$ ) to the inundated zone of Wells Pool. Therefore, we can assume that smolts crossing OKL do represent fish leaving the Okanogan River system, or at least they are entering a more reservoir-like environment where interspecific competition for food and space is likely to be less than in the river. Unfortunately, it is not possible to evaluate juvenile outmigration (or movement within the Columbia River) in the winter months because juvenile bypass facilities do not operate year round.

## Smolt-TO-ADULT RETURN

The 2014 is the earliest brood year that a PIT-based estimate of SAR could be calculated, because subyearlings were not PIT tagged for brood year 2013. The number of
returning adults from the PIT tagged subyearlings was so low that the accuracy of the estimate has considerable uncertainty. However, the fact that zero fish returned from the segregated subyearling program and only three adults returned from the integrated program suggests that PIT tags may not be a good tool for evaluating the SAR of subyearling Summer Chinook. PIT tagging resources may be better utilized increasing the sample size of yearling release groups. In future years the program will have more years of data to assess smolt to adult survival differences that can be used to provide insight on two options for the program: 1.) continue PIT tagging the subyearlings or 2.) rear fewer integrated subyearlings and, if possible, convert some of the integrated subyearlings to yearlings.

SAR for the most recent full brood returns (2012) was similar to the 5-year and higher than the long-term averages. It is likely that the SAR estimate is biased low because some recovery efforts were not expanded within RMIS, and also because some fish likely have yet to return. We had no way to obtain information necessary to do these expansions or to even speculate as the magnitude of the potential error introduced because of it. In the future, we suggest also using PIT tags as an independent, additional estimate of SAR.

## Adaptive Management and Lessons Learned

## The Annual Program Review (APR)

Each year the CJHP hosts a workshop to review and present findings from the previous year and plan for the upcoming fish production and science monitoring cycle. The APR was convened in April 2020 with the purpose of reviewing data collection efforts and results from 2019 and developing the hatchery implementation and monitoring plan for 2020 (Figure 30). This effort is focused on using adaptive management to guide the program. After a series of presentations highlighting the data collection activities and results, the group (CJHP staff and invited guests from Federal, State, PUD, and other organizations) used the In-Season Implementation Tool (ISIT) during the "Analysis" step (Figure 31). The group reviewed the ISIT input parameters for key assumptions, status and trends and decision rules to be sure that the best available information was included in the model. ISIT then used the pre-season Upper Columbia summer/fall Chinook Salmon forecast to provide an estimate of how the program could be implemented with respect to broodstock collection, harvest, weir, and hatchery ladder operations to achieve biological targets for 2020. APR materials with more details than what is provided within this report can be found at https://www.cct-fnw.com/annual-program-review/.

## Key Management Questions

Answering key management questions is an essential function of the CJHP and is central to the analysis and reporting steps in both the APR and this annual report. Management questions inform the development of the RM\&E activities, the CJHPs Key Management Questions (KMQs) are:

1. What is the current status and recent historical trend of the naturally spawning population in terms of Viable Salmonid Population (VSP) parameters? ${ }^{8}$
2. What is the current status and recent historical trends for hatchery returns and harvest?
3. Is the hatchery program meeting target in-hatchery performance standards?
4. Are the hatchery post-release targets met for survival, catch contribution and straying?
5. Are targets for total catch contribution and selectivity for HORs met?
6. Are there negative effects of the hatchery on the natural population?
7. Are assumptions about natural production potential valid?
8. How should the program be operated in the coming year?
[^8]
## Annual Planning Workflow

Figure 30. The Chief Joseph Hatchery's annual planning process and workflow.

Figure 31. The Chief Joseph Hatchery's analytical workflow.

## 2020 Run Size Forecast and Biological Targets

Run-size forecasts and updates are an early indicator for the biological targets for the coming season, through the Decision Rules outlined in the ISIT. The preseason forecast is based on brood year escapement and juvenile survival indicators and is generated through the Technical Advisory Committee (TAC) to the U.S. v. Oregon fish management agreement. As the season nears, this information is supplemented with return data from downstream dam counts. The pre-season forecast for Upper Columbia summer Chinook Salmon was 38,300. The pre-season forecast, and subsequent run updates from early dam counts, were used to predict the NOR and HOR run size for the Okanogan population. Hatchery broodstock and selective harvest targets are determined based on these estimates and the objectives for $\mathrm{pHOS}(<0.30)$ and $\mathrm{PNI}(>0.67)$. A regression analysis conducted within ISIT in preparation for the APR predicted that the pre-season forecast of 38,300 upper Columbia would yield 3,361 NORs and 5,146 HORs (Figure 32). The harvest and broodstock collection goals were established from this prediction. With a NOR run size just over 3,000 the broodstock collection recommendation for the integrated program was full production ( 439 NOB and 293 HOB) with $60 \%$ pNOB (Figure 32). Likewise, the segregated program should achieve full production with 581 HOB. The model predicted that 1,029 HORs would be captured in the terminal (above Wells Dam) fisheries and that no HORs could be removed at the weir. These efforts could result in 2,552 NOS and 1,689 HOS for a pHOS of $38 \%$ and a PNI of 0.61 . Under this modeling scenario the biological targets will likely not be met in 2020. As run size updates become available (through TAC) the ISIT outputs will be double checked until the final in-season check point on July 15, 2020. At that time the run size at Wells Dam will be input into ISIT and the final plan for broodstock and harvest will be updated. If the July 15 update includes more hatchery and natural fish than predicted, then harvest and removal of surplus fish at the weir and the hatchery ladder will be implemented by CCT and WDFW (through their mark-selective sport fishery). If the July 15 update includes less hatchery and natural fish than predicted, then CCT and WDFW will manage the harvest and removal of surplus fish in a way that will allow enough natural and hatchery-origin fish to escape to the Okanogan basin spawning grounds (NOS $\geq 5,250$, total escapement $\geq 7,500$ ) and also meet the pHOS objective of $<.30$.

*Expected values of Biological Targets if Management Targets are met.

## 2020 Key Assumptions

The CJHP reviews the key assumptions (working hypothesis) each year at the APR workshop. These assumptions directly affect the decision rules used to guide in-season management decisions. The program documents the changes and uses this information for future review and analysis (Figure 33).

## KEY ASSUMPTIONS-AHA

| Natural Production |  | Biological |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |

## 2020 Status and Trends

The recent performance of the population is a primary driver for determining how the hatchery program should be operated in the future. This was accomplished by updating and reviewing the status and trend information within five categories: (1) natural production, (2) hatchery production, (3) harvest, (4) migration, and (5) habitat (Figure 34).

| Return year | FPC Reported Dam Count at Wells thru 07/15 (excludes jacks) |  | \% of final count | $\begin{aligned} & \text { PUD Counts at Wells } \\ & \text { Dam } \end{aligned}$ |  | Estimated Return of Okanogan Origin Fish to Wells Dam |  |  | \%NOR | Terminal Harvest Above Wells |  |  |  |  |  |  |  |  |  |  |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |

## 2020 Decision Rules

The decision rules determine the targeted size of the hatchery program and the management of natural escapement abundance and composition. The purpose of the Decision Rules is to assure that the CJHP manages the hatchery, terminal fisheries, and weir to meet the guidelines for abundance, spawner composition, and distribution of the natural spawning escapement (Figure 35).

*Median, minimum and maximum values from 2021-2045 based on a single model run.

## Data Gaps and Research Needs

In a partnership with USGS, WDFW and the ONA, the CJHP is working to identify data gaps and applied research needs within the Okanogan Basin that would better inform hatchery management, increase available data for resource management decision making, and benefit overall salmonid recovery in the greater Columbia River basin. If funded in the future, the tasks identified could directly inform CJHP and other natural resource managers and aid in the decision-making process. Some of the data gaps and applied research needs that have been identified include:

1. Refined estimates (extent, fate, timing, and location) of summer/fall Chinook using the mainstem Columbia River above Wells Dam for spawning (i.e., straying), rather than returning to their natal Okanogan River using radio or acoustic telemetry.
2. Extent, fate, timing, and location of spawning Chinook in the Canadian portion of the Okanogan Basin.
3. Development and testing of a panel of microsatellites and/or single nucleotide polymorphisms (SNPs) for genotyping genetic stocks of Chinook salmon in the Okanogan Basin and upper-Columbia River, upstream of Wells dam, to identify and differentiate Okanogan summer- vs. fall- vs. spring-Chinook, as well as hatchery $\times$ hatchery, hatchery $\times$ wild, and wild $\times$ wild crosses of these various life-history types.
4. Utilization of advancements in thermal imaging/LiDAR or other remote sensing technologies combined with in-stream temperature loggers and ArcGIS/R Statistical Program (STARS \& FLoWs toolsets \& SSN package) to map current thermal refugia in the Okanogan basin and model potential changes resulting from climate change scenarios.
5. Development and/or adaptation of existing methods for better estimation of fine sediment loads per reach length in the Okanogan River to quantify effects on Chinook salmon spawning redds and productivity.
6. Design for testing fish tagging rate assumptions. PIT, radio, and genetic tagging emphasis.
7. Post-release mortality for various capture techniques including the purse seine, hatchery ladder, sport fishing, the weir, etc.

## APPENDIX A: Summer/fall Chinook

## Hatchery Operations and Production

The CJH's central facility is a 15-acre facility located immediately below Chief Joseph Dam along the right bank of the Columbia River at rkm 872 near Bridgeport, WA. There is one summer/fall Chinook CJH acclimation facility on the Okanogan River, Omak (rkm 51) acclimation pond. There is an additional acclimation facility on the Similkameen River (rkm 6.4) that is part of the CJH program but is operated by WDFW and funded by the CPUD.

Construction of the hatchery was completed in 2013 and broodstock were brought on station for the first time. The goal of the CJHP is to contribute to the increased abundance, productivity, temporal-spatial diversity, re-colonization of Chinook in the Okanogan Basin, and provide increased harvest for all fishers.

## Production Objectives

Full program production totals 2 million summer/fall Chinook. The summer/fall Chinook program incorporates both an integrated program ( 1.1 million smolts) supported by Okanogan River natural-origin broodstock and a segregated program (900,000 smolts) supported by hatchery-origin adults returning from the integrated program.

In 2019 , the summer/fall Chinook program production level did not meet full production as planned, due to higher-than-expected pre-spawn mortality on both the integrated and segregated summer/fall brood as well as poor incubation conditions due to a failing chiller.

## Summer/Fall Chinook Salmon

## BY 2018 Summer/FALL Chinook SaLmon Rearing and Release

Due to high pre-spawn mortality and reduced eyed egg survival, there was no integrated or segregated sub-yearling program for brood year 2018.

The yearling summer/fall Chinook rearing started earlier than anticipated due to a failing chiller. Marking was completed, for both the integrated and the segregated programs, on September 3, 2019. The segregated summer/fall Chinook were $100 \%$ adclipped, with a 100 k CWT group tagged. The integrated summer/fall Chinook were $100 \%$ AD/CWT. As shown in Table A 1 and Table A 2, ponding and rearing mortality for both programs were elevated as a result of the failing chiller The segregated fish were marked into rearing Pond B , while the integrated fish were marked into the lower raceways and reared until transfer to the acclimation ponds in late October. The segregated group was released on April 16th. Approximately 5,000 PIT tags were added to each group in October
2019. After subtracting shed tags and mortality, a total of 4,081 PIT tags were released from the segregated group ( 3,267 were detected at release).

Table A 1. Chief Joseph Hatchery brood year 2018 segregated summer/fall yearling rearing summary.

| Month | Total on hand | Mortality | Feed Fed | Fish per <br> pound | Cumulative <br> Survival (\%) |
| ---: | ---: | ---: | ---: | ---: | ---: |
| $12 / 31 / 2018$ | 258,944 | - | 20 | 1,172 | $100.00 \%$ |
| $1 / 31 / 2019$ | 202,200 | 56,744 | 262 | 340 | $78.09 \%$ |

The integrated summer/fall Chinook were shipped to the Omak Acclimation Pond and the Similkameen Acclimation Pond between October 24th and October 30th. Reporting for the Similkameen Pond will reside with WDFW through release.

## Omak Acclimation Pond

On October 26, 2018, Chief Joseph Hatchery staff transferred 133,940 Integrated BY 18 summer/fall Chinook from Chief Joseph Hatchery to the Omak Acclimation Pond. Approximately 5,000 PIT tags were added to the group in October 2019. At the time of transfer, the fish were approximately 16 fpp , and were programmed to be reared over winter, with a target size at release of 10 fpp . These fish were forced released April 30, 2020. After subtracting shed tags and mortality, a total of 4,532 PIT tags were released from this integrated group ( 3,780 were detected at release). Table A 2 illustrates feed fed, feeding rate, and mortality to date for the integrated summer/fall Chinook transferred to the Omak Acclimation Pond.

Table A 2. Omak Acclimation Pond BY 18 integrated yearling summer/fall Chinook rearing summary.

| Month | Total on hand | Mortality | Feed Fed | Fish per pound | Cumulative <br> Survival (\%) |
| :---: | :---: | :---: | :---: | :---: | :---: |

## Riverside Acclimation Pond

Riverside Acclimation Pond was not used to rear BY 2018 summer/fall Chinook but was utilized to rear BY 18 10j Spring Chinook.

## Similkameen Acclimation Pond

Similkameen Pond was used to rear yearling summer/fall Chinook per the WDFW program funded by CPUD. Adult broodstock used to generate the juveniles for BY 2018 were collected via the CCT purse seine as part of the transition to the collaborative CJH program. On October 30, 2019, Chief Joseph Hatchery staff transferred 120,387 summer/fall Chinook to the Similkameen Pond, with the assistance of WDFW's Eastbank Hatchery staff. At the time of transfer, the fish were approximately 16 fpp , and were programmed for over winter acclimation, with a target size at release of 10 fpp . These fish began volitional release on April 15th, with an end release date of April 30, 2020. Cumulative survival, at the date of transfer, was $67.3 \%$. Survival from transfer to release was 94.4\%.

## Cumulative egg to smolt survival

The target egg to smolt survival identified in the original summer/fall Chinook HGMP was $77.5 \%$ for sub-yearlings and $73.5 \%$ for yearlings (CCT 2008b). The cumulative egg to smolt survival, for the BY 2018 yearlings, was 45.5\% (52.8\% for the segregated program and 38.2 for the integrated program. The reduced survival rate is due to the chiller issues. There were no BY18 sub-yearling releases for either program.

## BY 2019 Summer/FALL Chinook SALMON

## 2019 Broodstock collection

Collection of summer/fall Chinook for BY 2018 occurred between July 8th and August 13th via the CCT purse seine operation at the mouth of the Okanogan River. Both hatchery-origin and natural-origin brood were collected to supply the integrated and segregated production programs at CJH. As the seine was being pursed, 9-meter transport barges approached the seine vessel and tied off on the opposite side. The broodstock transport barges have two transport tanks, a 300 gallon for HORs and a 600 gallon for NORs. Brood fish were removed from the seine and placed headfirst in a rubber tube, or boot, containing some water and handed to the staff on the barges for placement in the holding tanks. A maximum of 14 HOR and 28 NOR brood could be loaded per barge. Once full, or at the commencement of the purse seine haul, the barges returned to the offload area at Mosquito Park approximately 2 km away. The brood was then removed from the tanks by hand, placed into a boot, then delivered to one of two 2,500-gallon tanker trucks and transported 16 km to the hatchery.

Water temperatures were of major concern during these operations and monitored to minimize trauma to the adult brood. Okanogan River temperatures during July ranged from $67.5^{\circ} \mathrm{F}\left(19.7^{\circ} \mathrm{C}\right)$ to $78.4^{\circ} \mathrm{F}\left(25.8^{\circ} \mathrm{C}\right)$. In order to limit the effects of the temperature changes we monitored the temperature of all transport vessels and strived to not expose brood to changes greater than $8^{\circ} \mathrm{F}$. We accomplish this by utilizing both well water and surface water when filling the barges and transport tankers and monitoring our raceway temperatures.

A weekly quota was developed to ensure that brood collections occurred across as much of the summer/fall run timing as possible (Table A 3). If brood collection failed to meet the weekly quota it was adjusted the following week. However, due to low returns and to ensure overall broodstock goals were met, this quota was not followed and broodstock was collected as early as possible. The purse seine is only effective when there is a thermal barrier at the mouth of the Okanogan, therefore broodstock can only be collected there until late August or early September. Once at the hatchery, broodstock were offloaded 6 at a time into totes in order to inject with Draxxin and LA200 (liquamycin), with females receiving both while males only receiving LA200. Broodstock were then separated by program and sex and put into their designated raceways. The receiving water was approximately $57^{\circ} \mathrm{F}$. The adult ponds had a flow rate of 500 gpm , and an exchange rate of 54 minutes, representing a Flow Index (FI) of 0.56 and a Density Index (DI) of 0.08 at max capacity. Upon arrival, adult ponds were put on well water.

All adult ponds were treated a minimum of five days per week with formalin to control fungus at a rate of 1:6000, for one exchange. Additionally, brood fish were treated twice per week with Chloramine-T at 12 ppm for one exchange to control Columnaris bacteria. Diquat was also used under an INAD once Columnaris was detected in broodstock, which was from mid-August through October.

Table A 3. Chief Joseph Hatchery summer/fall Chinook weekly broodstock collection objectives and results for brood year 2019.

| Week | Weekly Quota ${ }^{1}$ |  | Cumulative Proportion | Cumulative Collection |  |
| :---: | :---: | :---: | :---: | :---: | :---: |

| ${ }^{1}$ Weekly collection short-fall to be added to following week's collection |  |  |  |  |  |
| ${ }^{2}$ Combined collection strategies in priority order: purse seine, tangle-net, Okanogan weir beach seine and CJH ladder |  |  |  |  |  |
| ${ }^{3}$ Combined collection strategies in priority order: purse seine, tangle-net, CJH ladder, Okanogan weir and beach seine |  |  |  |  |  |

A total of 553 HOB were collected including 302 females, 220 adult males and 31 jacks (Table A 4). However, it's believed some of these were mis-sexed as they entered the hatchery, so these numbers do not match exactly to the table. A total of 670 NOB were collected including 330 females, 284 adult males, and 56 jacks (Table A 4). Some of the fish initialed classified as jacks were actually adult males, this the difference from Table A 5. Due to low wild returns, some hatchery brood were allocated to the integrated program, which included 105 males, 127 females and 16 jacks. No steelhead or Bull trout were encountered during broodstock collection efforts.

Through the month of October 2019, there were 22 adult male and 31 adult female mortalities in the HOR brood, representing $91.3 \%$ and $89.0 \%$ cumulative pre-spawn survival to date, respectively. For the same time frame, 11 adult NOR summer/fall Chinook
males died, and 15 females died, representing $95.5 \%$ and $95.4 \%$ cumulative pre-spawn survival, respectively. (Table A 4) Brood fish, particularly females, suffered higher than anticipated mortality due to Columnaris disease, which affected us particularly hard once the well water in which these fish are held reached $>60^{\circ} \mathrm{F}$.

The cumulative pre spawn holding survival, for all summer/fall brood collected, was 89.9\% (including jack) for HOB and 95.8\% (including jacks) for NOB (Table A 4), the NOR program exceeded the survival goal of $90 \%$ while the HOB was just shy of the goal.

Table A 4. Chief Joseph Hatchery summer/fall Chinook Hatchery (HOB) and Natural (NOB) origin broodstock holding survival summary for brood year 2019. ( $\mathrm{M}=$ adult males, $\mathrm{J}=$ jacks and $\mathrm{F}=$ adult females). The survival standard for this life stage was $90 \%$.

Hatchery staff began collection of NOR brood from the weir on August 27, 2019. Collections off the weir were slow and only 8 wild females and 2 hatchery females were caught and transferred to the hatchery for broodstock. Fish were transferred from the weir trap manually.

The fish were then transported approximately 32 km to Chief Joseph Hatchery where they were held in the broodstock raceways until the first spawn date the first week in October. We recognize that fish collected late may have arrived at any point in their run timing; however, the efforts to collect fish in late August into September at least offer the opportunity to include fish that arrive later in the run timing.

## Spawning

Spawning of summer/fall Chinook began on October 1, 2019, with the segregated program, and continued through October 29, 2019. Beginning with the 2018 brood year, the segregated and integrated programs will be spawned on separate days. As with the
spring Chinook, the summer/fall Chinook program is also 100\% ELISA sampled. For the 2019 brood, there were no eggs culled for either program in 2019.

Total NOB spawned included 273 males, 37 jacks, and 314 females. (Table A 5) Total HOR spawn included 198 males, 16 jacks, and 248 females. Total eyed egg take for the season was $1,988,520$. Egg survival from green egg to eyed egg for NOB averaged 82.9\% (Table A 5). Egg survival for HOB averaged $87.2 \%$. Survival was lower than the key assumption of (90\%) for this life stage.

Table A 5. Chief Joseph Hatchery brood year 2019 summer/fall Chinook spawning and incubation results.

## Broodstock origin

Broodstock were interrogated for coded-wire tags by program throughout October and the first week of November. Beginning October $1^{\text {st }}$, segregated fish were spawned on Tuesday of each week, while integrated fish were spawned on Wednesdays. A total of twelve spawning events occurred in 2019. All ad-clipped chinook incorporated in the integrated and segregated programs were sampled at $100 \%$ for CWTs regardless of electronic detection via T-wand. Collected samples were then frozen until mid-December where CWTs are extracted and analyzed in the laboratory during winter months.

All broodstock collected for the summer/fall Chinook segregated program came from an Upper Columbia River hatchery program. The CJH integrated program was the largest contributor to segregated brood with ( $\mathrm{n}=297$ ) $58.8 \%$ of adults coming from either the Similkameen or Omak Pond (Table A 6). Other Upper Columbia River Hatcheries contributed ( $\mathrm{n}=79$ ) 15.4\%, most of which were from Wells Hatchery (8.7\%) and Carlton A.P. (3.1\%). A large portion of snouts ( $\mathrm{n}=106$ ) indicated detection during spawning events, but a coded-wire tag was not found during extraction. Reasons for this include but are not
limited to rapidly shaking a Northwest Marine Technologies (NMT) T-Wand when scanning for a CWT (false positive in the field), failure to detect a tag in the lab (false negative), metals in the soil that transfer to a fish during handling or hooks or other metal debris in the fish's head. The unknown component represents $20.9 \%$ of the 2019 segregated brood (Table A 6). The mark rate for brood year 2013-2017 segregated releases vary between $99 \%$ and $24 \%$ ad-clipped + CWT however, overall mark rate between these brood years averages $68.5 \%$. All summer/fall Chinook programs upstream of Priest Rapids Dam are expected to have a $100 \%$ tag rate (except for CJH segregated). We would expect a portion of no CWT detection in the lab with the CJH segregated adult returns after adjusting for tag loss, the number of estimated non-CWT recoveries ( $\mathrm{n}=106$ ) can be assigned to the segregated CJH program. The overall composition of the segregated program (tagged and non-tagged) to the segregated brood was 25.8\%.

Table A 6. Composition of hatchery-origin brood, by program, collected for the CJH segregated program in 2019.

| Category | Hatchery Program | Brood | $\%$ of brood |  |
| :---: | :---: | :---: | :---: | :---: |
| Okanogan Integrated | Similkameen | 186 | $36.8 \%$ |  |
|  | Omak Pond | 108 | $21.3 \%$ | $58.8 \%$ |
|  | Natural Origin | 3 | $<1.0 \%$ |  |
| CJH Segregated | Chief Joseph <br> Chief Joseph (non- <br> tagged) | 24 | 106 | $20.9 \%$ |

*Brood values are adjusted to account for segregated no tag fish and are rounded to the nearest whole number.

## Integrated Program Broodstock Age Structure

Scales are taken from summer/fall Chinook integrated Program broodstock in order to capture the age of successfully spawned fish. In 2019, the integrated and segregated programs were comprised of mostly four and five-year old male and female fish (Figure A 1).

Male Integrated Summer Chinook Broodstock Total Age

Male Integrated Summer Chinook Broodstock Salt Age

Figure A 1. The total and salt ages of the 2019 broodstock, males and females, collected for the Okanogan summer/fall Chinook integrated program.

## Segregated Program Broodstock Age Structure

Coded wire tags are extracted from summer/fall Chinook segregated program broodstock and later read in order to capture the age of successfully spawned fish (Figure A 2).

Female Segregated Summer Chinook Broodstock Total Age

Female Segregated Summer Chinook
Broodstock Salt Age

Figure A 2. The total and salt ages of the 2019 broodstock, males and females, collected for the Chief Joseph Hatchery segregated program.

## Incubation

Eggs from each female summer/fall Chinook were placed in individual incubators (Heath Trays) and remained individually incubated until ELISA results were obtained. Once eye-up occurred, eggs from any moderate and high ELISA would be removed; No eggs were discarded from either program. The cull rate for this production plan allows for a rate of $5 \%$ for segregated and $3 \%$ for integrated. After eye-up, egg mortality was removed, and the eggs were inventoried and put back into their individual trays for hatching. Incubation water temperatures was initially manipulated to the level necessary to synchronize the hatching and ponding of the spawn takes throughout October and November 2019 and to achieve the size-at-release target for both yearling and sub-yearling summer/fall Chinook programs.

## Rearing

The first group of brood year 2019 sub-yearlings were brought out of incubation and transferred into early rearing troughs in early February 2020 (Table A 7). During this time, the group was introduced to feed in the early rearing troughs and reared for a period of two weeks. After the initial rearing period inside, they were transferred outside to the standard raceways via the fry transfer line. No inventories were taken during transfers, to prevent excess handling stress.

The first group of integrated yearlings were brought out of incubation and transferred into early rearing troughs in late February 2020 while the first group of segregated yearlings were brought out in early March 2020 (Table A 7). During this time, the group was introduced to feed in the early rearing troughs and reared for a period of two weeks. After the initial rearing period inside, they were transferred outside to the standard raceways via the fry transfer line. No inventories were taken during transfers, to prevent excess handling stress.

Table A 6. Chief Joseph Hatchery brood year 2019 summer/fall Chinook yearling rearing summary.

|  | Month | Total on hand | Mortality | Feed Fed | Fish per pound | Cumulative Survival (\%) |

## Chief Joseph Hatchery Ladder

The CJH ladder is operated with the primary purpose of adult management (reducing pHOS) but can also be utilized to collect brood for the segregated program in years of low abundance or if the purse seine is not effective due to environmental conditions. The CJH fish ladder began operation on May 20, 2019, for spring chinook broodstock collection, with the first summer/fall chinook adult management activities occurring on July 25th. All hatchery Chinook and Sockeye were removed from the ladder and utilized for Tribal subsistence and ceremonial food purposes. All steelhead and NOR Chinook were returned to the river via a water-to-water transfer.

From May 20th thru August 28th, 1,445 hatchery-origin summer/fall Chinook were removed at the CJH ladder and were utilized for tribal subsistence purposes (Table A 8). There was 1 hatchery adult and 1 hatchery jack returned to river during the early stages of ladder operation in June. A total of 15 natural-origin summer/fall Chinook, 19 NOR steelhead and 65 HOR steelhead were trapped, handled, and released back to the Columbia River (Tables A 9 and A 10). The encounter/handling and release of 19 NOR steelhead represents $16 \%$ of the allowable incidental take provided in the Biological Opinion ( BiOp ) for Chief Joseph Hatchery collection facilities (NMFS 2008). There were no observed immediate steelhead mortalities during the ladder operations in 2019.

[^9]The ladder was closed and dewatered on August 31, 2019 for the season. The protocol was to sample 20\% (one of five) of the adipose-clipped summer/fall Chinook for code-wire tags (CWT). Snouts with positive CWT detection were held frozen until December 2019 when CWT extraction and reading took place in the Chief Joseph Hatchery lab. Recovery data were expanded by the tag rate at the hatchery of origin and the sample rate at the ladder. Please refer to the Methods section for details on the expansion process for recovered tags. Beginning with jacks in 2016, snouts without a tag were assumed to be from the CJH segregated program.

Six summer/fall Chinook hatchery programs were encountered at the CJH ladder in 2019, with the majority coming from the CJH segregated program (54\%), Wells Hatchery (30\%) and Chelan Falls (8\%) (Table A 12). Approximately half of the recoveries were from
ad-clipped, non-coded wire tagged (CWT) fish and are presumed to be from the CJH segregated program since this is the only one above Priest Rapids that releases ad-clipped, non-CWT fish.

Table A 10. Summary of summer/fall Chinook coded-wire tags encountered and expansions for the CJH ladder in 2019.

| Category | Hatchery Program | \# Tags | Expanded Abundance | \% of <br> Ladder <br> Surplus |

| Total |  | 273 | 1404.0 | 100\% |

Table A 11. Percent of CJH ladder surplus adult (age 4+) summer/fall Chinook each year estimated to be from various facilities based on CWT assessment. Similkameen includes some returns from Bonaparte Pond releases (2010 and 2011). Chelan includes returns from the Turtle Rock program (2010 and 2011). 2017 was the first year of adults (4-year-olds) to CJH. 2018 was the first return year with a full complement of brood years in the return (through age 5).

${ }^{\text {a }} 25$ additional carcasses were sampled on the Similkameen and 46 on the Okanogan without any reach designation.
${ }^{\mathrm{b}}$ One additional carcass was sampled on the Similkameen without any reach designation.
c 793 carcasses were sampled on the Similkameen before initiation of spawning (pre-spawn mortality) and an additional 40 carcasses were sampled on the Okanogan. The cause of the high mortality (Ichthyophthirius multifilis and Flavobacterium columnarae) was exacerbated by high river temperatures.
${ }^{\text {d }}$ In 2013, carcass recoveries were combined in reaches $\mathrm{O}-3$ and $\mathrm{O}-4$, and $\mathrm{S}-1$ and $\mathrm{S}-2$. Then re-apportioned based on redd counts within each reach.
e 2013 data have been updated to reflect age and origin data acquired from scale reading since the publication of the 2013 annual report

## Age at Maturity

## APPENDIX D

## Glossary of Terms, Acronyms, and Abbreviations

The following is a list of key terms and variables used in the Chief Joseph Hatchery Program and in this Annual Report. This is not a complete list but provides many of the main terms used in this report or that will likely be used in future CJHP Annual Report.

Accord/MOA = A ten-year agreement (2008-2018) between BPA and the CCT whereas BPA agreed to fund pre-determined fish and wildlife projects and CCT agreed not to sue the Action Agencies regarding the BiOp for the FCRPS.

CJHP Master Plan = A three-step development and review process required for all new hatcheries funded by BPA in the Columbia Basin.
eDNA = environmental DNA; dissolved or cell-bound DNA that persists in the environment.
Escapement Target $=$ Number of fish of all origins targeted to pass upstream of the Okanogan Adult Fish weir

HOB = the number of hatchery-origin fish used as hatchery broodstock.
$\mathbf{H O R}=$ hatchery-origin recruit. The number of HORs equals the sum of HOS + HOB + hatchery-origin fish intercepted in fisheries.

HOR Terminal Run Size = Number of Chief Joseph Hatchery HORs returning to Wells Dam HOS = the number of hatchery-origin fish spawning naturally.

Juvenile Abundance = annual abundance of out-migrant juveniles estimated by expanding data from juveniles captured at the rotary screw trap.

Met Comp = Methow composite Spring Chinook. These fish are part of the Winthrop NFH program and are intended to be used for the Okanogan reintroduction pending approval under section 10(j) of the ESA.

NOB = the number of natural-origin fish used as hatchery broodstock.
NOR = natural-origin recruit. The number of NOR's equals the sum of NOB, + NOS + natural-origin fish intercepted in fisheries.

NOR Terminal Run Size = Number of Okanogan (and Similkameen, combined) NOR's returning to Wells Dam.

NOS $=$ the number of natural-origin fish spawning naturally.
$\mathbf{p H O S}=$ proportion of natural spawners composed of HORs. Equals HOS/ (NOS + HOS).

PNI = proportion of natural influence on a composite hatchery-/natural-origin population. Can also be thought of as the percentage of time the genes of a composite population spend in the natural environment. Equals 1 - pNOB/ (pNOB + pHOS).
pNOB = proportion of hatchery broodstock composed of NORs. Equals NOB/ (HOB + NOB).
$\mathbf{S A R}=$ smolt to adult return.
Recovery Plans = Federally required plans under the Endangered Species Act that describe species status, recovery criteria and expected restoration actions.

Relative Reproductive Success = The probability that an HOR produce adult offspring and summer/fall expressed as a fraction of the same probability for a NOR

Spatial Distribution = Geographic spawning distribution of adult salmon.
Spawner Abundance $=$ Total number of adult spawners each year.
Subbasin Plans = Plans developed in the early 2000s for the NPCC project funding process describing "limiting factors" used for development of regional recovery and protection strategies.

Total NOR Recruitment = Annual number of adult recruits (catch plus escapement)

```
AHA = All H Analyzer
APPT = Annual Program Planning Tool
APR = Annual Program Review
BiOp = Biological Opinion
BKD = Bacterial Kidney Disease
BPA = Bonneville Power Administration
CA = Coordinated Assessments
CBFWA = Columbia Basin Fish and Wildlife Authority
CCT = Confederated Tribes of the Colville Indian Reservation
cfs = Cubic feet per second
CJH = Chief Joseph Hatchery
CJHP = Chief Joseph Hatchery Program
Colville Tribes = Confederated Tribes of the Colville Reservation
CTFWP = Colville Tribes Fish &Wildlife Program
CRITFC = Columbia River Inter-Tribal Fish Commission
CWT = Coded Wire Tag
DI = Density Index
```

```
DPS = Distinct Population Segment
EDT = Ecosystem Diagnostic & Treatment
ELISA = Enzyme-Linked Immunosorbent Assay
ESA = Endangered Species Act
ESU = Evolutionarily Significant Unit
FCRPS = Federal Columbia River Power System
FI = Flow Index
FPP = Fish per pound
FWS = U.S. Fish and Wildlife Service
GIS = Geographic Information System
gpm = gallons per minute
GPS = Global Positioning System
HCP = Habitat Conservation Plan(s)
HGMP = Hatchery Genetic Management Plan(s)
HSRG = Hatchery Science Review Group
ISIT = In-season Implementation Tool
ISRP = Independent Scientific Review Panel
KMQ = Key Management Questions
LNFH = Leavenworth National Fish Hatchery
NEPA = National Environmental Policy Act
NMFS = National Marine Fisheries Service
NOAA = National Oceanic and Atmospheric Administration
NPCC = Northwest Power and Conservation Council
OBMEP = Okanogan Basin Monitoring and Evaluation Program
ODFW = Oregon Department of Fish and Wildlife
ONA = Okanagan Nation Alliance
PBT = Parental Based Tagging
PIT = Passive Integrated Transponder
PNAMP = Pacific Northwest Aquatic Monitoring Partnership
PSMFC = Pacific States Marine Fisheries Commission
PTAGIS = PIT Tag Information System
PUD = Public Utility District
```

RKM = River Kilometer
RM = River Mile
RMIS = Regional Mark Information System
RM\&E = Research, Monitoring, and Evaluation
RST = Rotary Screw Trap
SNP = Single Nucleotide Polymorphism
TAC $=$ Technical Advisory Committee
TRMP = Tribal Resources Management Plan
$\mathbf{T U}=$ Temperature Unit
UCSRB = Upper Columbia Salmon Recovery Board
USGS = U.S. Geological Survey
WDFW = Washington Department of Fish and Wildlife
WNFH = Winthrop National Fish Hatchery

## Appendix E

# Technical Memorandum: Minijack Rates for 2019 Chief Joseph Hatchery Integrated and Segregated Chinook Releases 

Date: 8 July 2019
From: John Rohrback; john.rohrback @colvilletribes.com (509) 634-1068
To: Andrea Pearl, Matthew McDaniel, Casey Baldwin, Anthony Cleveland, Jim Andrews
CC: Kirk Truscott
Subject: Minijack rates for 2019 Chief Joseph Hatchery Chinook release groups

## Background

This technical memorandum will summarize the results of gonadal-somatic index (GSI) sampling conducted by the Chief Joseph Hatchery Program (CJHP) in May 2019 and provide estimates for the rate of early maturation ("minijack rate") from each yearling group released in 2019 (brood year 2017).

Early maturation of male hatchery-origin Chinook salmon is a concern throughout the Columbia River basin, with some hatchery releases exhibiting minijack rates of over 70\% (Harstad et al. 2014). The production of high levels of minijacks is not consistent with the goals and objectives of the CJHP, which intends to produce adult fish for harvest and conservation. Additionally, the National Marine Fisheries Service (NMFS) requested that the Confederated Tribes of the Colville Indian Reservation (CCT) include an evaluation of early maturation on all yearling Chinook programs because early maturation is considered a 'take surrogate' for potential competitive interactions with natural-origin fish (NMFS 2017). The reporting requirements of NMFS were based on the methodology described in Harstad et al. (2014) that used a blood plasma test to evaluate the level of 11-ketotestosterone to estimate initiation of male maturation as mini-jacks. Absent funding to implement the 11-KT method, the CJHP elected to use a visual
and GSI approach to evaluate early maturation. The GSI approach has been implemented by the USFWS for the Leavenworth complex for a number of years with good success (Matt Cooper, personal communication). The CJHP staff believe the GSI evaluation presented herein meets the intent of the reporting requirement (\#6) described in the NMFS determination letter.

## Methods

Prior to release, approximately 300 fish were collected from each yearling 2019 Chief Joseph Hatchery (CJH) release group for dissection and examination. In contrast to 2018, these fish were held at CJH after their cohorts had been released for approximately one month. This was to allow for additional maturation and facilitate distinction between mature and immature fish. The release groups are:

- Segregated spring Chinook; released from Chief Joseph Hatchery, hatchery-origin broodstock collected at the Chief Joseph Hatchery Ladder
- Segregated summer/fall Chinook; released from Chief Joseph Hatchery, hatchery-origin broodstock collected from the Columbia River near the mouth of the Okanogan River
- Integrated spring Chinook; released from the Riverside Acclimation Pond, natural-origin MetComp broodstock from Winthrop National Fish Hatchery
- Integrated summer/fall Chinook; released from the Omak Acclimation Pond, naturalorigin broodstock primarily of Okanogan-origin stock
- Integrated summer/fall Chinook; released from the Similkameen Acclimation Pond, natural-origin broodstock primarily of Okanogan-origin stock
Fish were euthanized with MS-222 and processed in accordance with the USFWS GSI sampling protocol (Pfannenstein 2016, see Appendix A). Males were classified as either mature or immature based on a visual inspection of the gonads, and the gonadal-somatic index (GSI) was also calculated for statistical estimation of minijack rates for each release group.

After data was collected, GSI values were analyzed using a mixture model (Medeiros, see Appendix B) in an attempt to identify immature and mature sub-populations and estimate the minijack rate within each sampled release group.

## Results

Based on the visual assessment of maturity, CJH yearlings overall displayed moderate rates of early maturity ( $14.25 \%-37.41 \%$, Table 1 ). The mixture model was fit to all release groups except Similkameen summer/falls and encompassed a similar range of expected rates of early maturation (19.02\%-43.06\%, Table 1). A distinct separation in Log 10 GSI between immature and mature fish was apparent only in the segregated spring Chinook release group. Such a break also seemed to occur in the Similkameen integrated summer/fall Chinook release group, but it could not be captured by the mixture model. Nevertheless, a cutoff value for classifying sampled fish as mature or immature, and therefore a minijack rate, could be modeled for all groups except
for integrated summer/fall Chinook released into the Similkameen River (Figures 1-4). Histograms that display the distribution of Log 10 GSI for each sampled release group are presented in Figures 1-5.

Annual rates of early maturation are recorded in Table 2.
Table 1. Mini-jack rate for each Chief Joseph Hatchery release group from brood year 2017.

| Release Group | Release <br> Location | Males <br> Examined | Visually classified immature | Visually classified mature | $\begin{gathered} \text { Visual } \\ \text { mini-jack } \\ \text { Rate } \end{gathered}$ | Modeled mini-jack rate |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| Segregated Spring Yearlings | Chief Joseph Hatchery | 163 | 112 | 51 | 31.29\% | 19.02\% |
| Segregated Summer/Fal 1 Yearlings | Chief Joseph Hatchery | 147 | 126 | 21 | 14.29\% | 43.06\% |
| Integrated Spring Yearlings | Riverside Acclimation Pond | 147 | 92 | 55 | 37.41\% | 42.17\% |

| Integrated | Similkamee <br> n |  |  |  |  |  |
| Summer/Fal 1 Yearlings | Acclimation Pond | 134 | 114 | 20 | 14.25\% | N/A |

## BY17 CJH Segregated Spring Chinook

Figure 1. Distribution of Log 10 GSI for the segregated spring Chinook released from the Chief Joseph Hatchery. The cutoff value is marked by the vertical green dashed line. It marks the point of differentiation between immature fish (appearing to the left of the cutoff line) and mature fish (appearing to the right of the line). The solid blue line shows the distribution function of immature fish, and the solid red line shows the distribution function of mature fish.

## BY17 CJH Segregated Summer Chinook

Figure 2. Distribution of Log 10 GSI for the segregated summer/fall Chinook released from the Chief Joseph Hatchery. The cutoff value is marked by the vertical green dashed line. It marks the point of differentiation between immature fish (appearing to the left of the cutoff line) and mature fish (appearing to the right of the line). The solid blue line shows the distribution function of immature fish, and the solid red line shows the distribution function of mature fish.

## BY17 Riverside Integrated Spring Chinook

Figure 3. Distribution of Log10 GSI for the integrated spring Chinook released from the Riverside Acclimation Pond. The cutoff value is marked by the vertical green dashed line. It marks the point of differentiation between immature fish (appearing to the left of the cutoff line) and mature fish (appearing to the right of the line). The solid blue line shows the distribution function of immature fish, and the solid red line shows the distribution function of mature fish.

## BY17 Omak Integrated Summer Chinook

Figure 4. Distribution of Log10 GSI for the integrated summer/fall Chinook released from the Omak Acclimation Pond. The cutoff value is marked by the vertical green dashed line. It marks the point of differentiation between immature fish (appearing to the left of the cutoff line) and mature fish (appearing to the right of the line). The solid blue line shows the distribution function of immature fish, and the solid red line shows the distribution function of mature fish.

Figure 5. Distribution of Log10 GSI for the integrated summer/fall Chinook released from the Similkameen Acclimation Pond. Since a cutoff value differentiating immature and mature subpopulations was not determinable, subpopulations distribution functions and the cutoff value are not displayed.

Table 2. Annual predicted minijack rate for all CJH release groups.

| Year |  | CJH <br> Segregated <br> Spring <br> Chinook | CJH <br> Segregated <br> Summer/Fall <br> Chinook | Riverside <br> Integrated <br> Spring <br> Chinook | Omak Integrated <br> Summer/Fall <br> Chinook | Similkameen <br> Integrated <br> Summer/Fall <br> Chinook |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  | Visual <br> Estimate | $3.23 \%$ | $4.29 \%$ | $1.34 \%$ | $0.00 \%$ | $0.75 \%$ |
|  | Modeled <br> Estimate | $4.52 \%$ | N/A | N/A | N/A | N/A |
| 2019 | Visual <br> Estimate | $31.29 \%$ | $14.29 \%$ | $37.41 \%$ | $19.63 \%$ | N/A |

## Discussion and Recommendations

The data and analyses presented herein suggest that the early maturation rate for brood year 2017 releases was much higher than that of brood year 2016 Chinook. Despite a year-over-year increase in minijack rates from CJH releases, the predicted rates minijack rates for all CJH release groups in 2019 were still comparable to other Columbia River hatchery programs (Harstad et al. 2014).

Although the range of rates of minijacking between release groups estimated by visual assessment and the mixture model were similar, there was not perfect agreement between the two methodologies. This predictive exercise should be paired with a retrospective analysis which uses PIT tag data to estimate actual rates of minijacking within each release group. Such an analysis could shed light on whether one method of estimating minijack rate is more accurate than the other. Or, if PIT analysis shows rates of early maturation that are strongly divergent from both of the GSI-based estimates, that could provide a basis for future implementation of 11KT testing.

Visual determination of maturity state is subjective and is likely only useful when the state of maturity has progressed to the point where it becomes so clear that observer error or bias can be overcome. Similarly, the mixture model relies on an ability to differentiate between two distinct, normally distributed populations within a sample. Holding the fish for an additional month postrelease allowed more time for gonadal development in the early maturing fish. This allowed for mixture model convergence at a much higher rate than in 2018 and may have contributed to reducing Type II error in the visual determination. Although this implies that the minijack rates
reported in 2018 may have been artificially low, such a determination cannot be confidently made without supportive PIT tag data. It is recommended that a holdover period similar to what was employed in 2019 be maintained in future years.

NAD Supplies List [Bracketed numbers are minimum numbers needed for ONE CREW, 4-6 people, for 300 fish]

Daily consumables:

- Data sheets: Length/weight sheet AND gonad weight sheet (Rite in the Rain) Paper number tabs (Rite in the Rain)
- Paper towels (brown single fold, $\sim 100 /$ pack)

General:

- [3] Clipboards
- [3] Mechanical pencils + lead
- [2] Tables
- [4] Chairs
- [4] Buckets to raise table (small white)
- [2] Power strips
- [2] Extension cords
- Garbage bags
- Absorbent lab paper to cover work surfaces (roll)
- Duct tape
- Large scissors and a sharpie
- Extra batteries (9 volt + AA)
- Buckets + aerators
- Counting clickers
- Camera/iPad

Length and weight station:

- Tricane Methanesulfonate (MS 222)
- [1] Tub for fish
- [1] Dip net
- [1] Pit scanner + [1] stand
- [4] large sponges + [1] cookie tray
- [1] Scale for weights + [1] smolt weight pan
- [1] Length board

## Dissecting station:

- [1 or 2] Micro scale (minimum power 0.001 g ) + power cords
- [4] Scissors + [4] tweezers
- [2] Buckets for garbage (5 gallon)
- S/M/L glove boxes
- Weigh boats for scales
- Portable lights

## 'NAD Sampling How-To

1. Prepare TWO different data sheets: one with fish ID, fork length, weight, smolt index (0-3), pit \#, and the other with fish ID, sex (M/F), maturation (0-2), gonad weight. Each fish will have an individual fish ID number, which will be matched up during data entry. Measure fish body weight to the nearest 0.1 g and gonad weight to 0.0001 g .

Date: $\qquad$ - 20 $\qquad$
Hatchery: $\qquad$ Species/Stock $\qquad$
Group: $\qquad$ Bank: $\qquad$ Raceway(s) $\qquad$
Other:
Smolt index (0= unk, 1= parr, 2= trans, 3=smolt) Maturity (0=unknown, 1=immature, 2=mature)

| Fish ID\# | Sex (M/F) | Maturity (0-2) | Gonad Wt. <br> (gms) | Comment |
| :---: | :---: | :---: | :---: | :---: |
|  |  |  |  |  |
|  |  |  |  |  |
|  |  |  |  |  |
|  |  |  |  |  |

2. Collect fish from hatchery ponds. Random sample? Keep different ponds separate? CWT? Pit Tag?
3. Set up stations. Note length/weight station is at standing height.

4. Smolt index: 1. Parr, dark marks (bottom fish), 2. Transitional, faded marks (middle fish), 3. Smolt, silver, no marks (top fish)

5. Set out 15-20 fish in a row on the sponges. Add number tags to fish. Assess smolt index while all fish are in the line. Obtain weights and lengths, place on paper towel to pass to the dissecting crew.

6. Fish dissection: Cut open belly from vent (shallow incision), cut behind gill, open fish and gently remove guts to expose air bladder. Both male and female gonads are located on the top/edge of the air bladder (orange arrow on mature male).

7. Female identification: 1. Ovary forms a point and then narrows to oviduct - thread like (green arrow) 2. Ovary is angular, has ridge (blue arrow), 3. Granulated (orange arrow), 4. Color (red arrow) is not a good indicator as it can vary from pink to white.

8. Immature male identification: Testes are thready throughout, smooth and round, no development or thickness (green arrows).

9. Mature male identification: Testes thicken, become white/translucent, smooth, tapers to tail.

10. Visually identify fish sex. If female, record fish number and sex on datasheet. If male, visually identify if immature or mature PRIOR to weighing gonads, record visual call and then remove and weigh gonads.
11. Removal of testes for weighing: Use a fine point tweezers, start as near to the anterior insertion as possible (orange arrow), gently lift the entirety of the 'nad off of air bladder down to the tail (blue arrow). Place on the back of your hand and remove second 'nad. Weigh both complete testes. If you were only able to remove one, double the weight on the datasheet, and note that only one was weighed.

12. To use the scale: Close all doors, zero balance, open door, place 'nads in weight boat, close doors, wait for number to stabilize. 'Nads will evaporate and become lighter in a short period of time.
13. Enjoy all the 'nad jokes you can handle and interagency mingling!

## NAD Data Summary and Analysis Methods

- Enter data and QA/QC work, make sure to include specific banks/raceways.
- Calculate Gonadosomatic Index (GSI = gonad weight (g) / weight (g) *100).
- Calculate Condition Factor (K=(105) *weight/length ${ }^{3}$ ).
- Calculate the Log10(GSI) and graph the frequencies in a histogram to visually see the bimodal pattern of the immature and mature males. Use this graph to determine the GSI threshold that separates immature and mature males.

- From the GSI threshold, calculate the counts, percentages, average length, weight, and condition factor for immature and mature males.
- In a summary table, for both males and females, include gender counts, percentages, and average length, weight, and condition factors. For males, summarize visual counts for immature and mature fish and the percentage of mature fish. Summarize GSI counts and percent for immature and mature fish and list the average length, weigh, and condition factor for each group. Make sure to note what GSI threshold was used.

Table x. Leavenworth National Fish Hatchery Complex juvenile pre-release/early-maturation sampling, April 5-8, 2016.

| Pre-Release Data |  |  |  |  |  |  |  | Visual Count |  |  | GSI* Count |  |  | GSI Immature Male Averages |  |  | GSI Mature Male Averages |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| Site | Species | Gender | Count | Percent | Ln | Wt | K | Immature | Mature | \% | Immature | Mature | \% | Ln | Wt | K | Ln | Wt | K |

- Perform additional statistics as desired (Were the raceways different? Feed differences? Circular tanks vs. raceways, differences between years, etc). Normality, chi-squared goodness of fit, t-test, Anova, etc.

## NAD Sampling Notes (What worked? What didn't?)

- Print off more data sheets than you think you need. The two data sheet system works best; the dissectors can record their own data.
- Have two people per dissection scale- the more people that use the scale, the more awkward it gets.
- Weighing all male gonads vs. writing "T" for threads/trace? What is best for level of accuracy desired?
- Can we eyeball maturation, i.e., distinguish between 1 (immature) and 2 (mature)?
- Can maturation be determined by gonad weight or \% GSI? OR is maturation highly variable and dependent on stock and/or sampling date?
- For data analysis, "T" weight gonads were given a gonad weight of 0.00001 g for a visual representation on the graphs.
- Steelhead that were expressing milt were assigned a maturity level of 3, and were counted, but not weighed. For data analysis, they were assigned a gonad weight of 1.0 g in order to calculate GSI and to be visually represented on the graphs.

Thank you to everyone who participated in the 2016 'NAD sampling: USFWS, WDFW, Chelan PUD, Douglas PUD and Grant PUD!

## Mixture model and maturity cutoff calculation

## For Data Analyses: Determine cutoff for maturing vs. non-maturing fish

From Dr. Lea Medeiros, University of Idaho Post-Doc
\# Example using C16 11-kT data from minijack study
Export list of Log(conc) or Conc (and convert to Log(conc) once imported into R studio)
Import C16 CSV using import button in rStudio

- Make sure that the separator is set to "Comma" if importing a CSV... sometimes wants to import as whitespace
Copy and paste the code below the line into rStudio
\# Load the appropriate packages
library(mixtools)
library(diptest)
library(Hmisc)
\# Define variables (columns in imported CSV)
LC=C16\$Log
\# Only define variables for which you have columns
\# If value shows up as factor instead of num you have a non-numeric value in the CSV
\# Determine if distribution is bimodal
dip.test(LC) \# returns dip statistic (D) and p-value, as well as what hypothesis (i.e., initial or alternate) to accept. If alternate is accepted, proceed.
\# Determine the variables for the normal curves in the bimodal distribution
model=normalmixEM(LC)
plot(model, whichplots $=2$ )
\#Make sure things look right but won't actually use this graph as it plots on a density scale and may cause confusion. However, this should look pretty spot on (final graph will just be scaled up by a constant determined later on) so make sure that the point where the two curves intersect is where you are expecting the cutoff to be
\# Determine cutoff
index.lower <- which.min(model\$mu)
find.cutoff <- function(proba=0.5, i=index.lower) \{
\#\# Cutoff such that $\operatorname{Pr}[$ drawn from bad component] $==$ proba
f <- function(x) \{
proba - (model\$lambda[i]*dnorm(x, model\$mu[i], model\$sigma[i]) /
(model\$lambda[1]*dnorm(x, model\$mu[1], model\$sigma[1]) +
model\$lambda[2]*dnorm(x, model\$mu[2], model\$sigma[2])))
\}
return(uniroot(f=f, lower=-2, upper=2)\$root) \# Careful with division by zero if changing lower and upper
\}
cutoff <- c(find.cutoff(proba=0.5)) \# Can change to have range around $50 / 50$ probability, but this is the value we use to determine if a fish is maturing or not
\# Define curves from normalmixEM for plotting on histogram
$\mathrm{h}<-\operatorname{hist}(\mathrm{LC}, \mathrm{ylim}=\mathrm{c}(0,140)$,breaks=20) \# will produce basic histogram of data used for stats it produces; may need to alter ylim to reflect frequency of tallest bin and breaks xfit <- seq( $-0.7,1.4$,length $=200$ )
\#First number should minimum bin, second number should be maximum bin, length is number of plots pointed (higher number = smoother curve... to a point)
yfit1 <- model\$lambda[1]*dnorm(xfit,mean=model\$mu[1],sd=model\$sigma[1])
yfit2 <- model\$lambda[2]*dnorm(xfit,mean=model\$mu[2],sd=model\$sigma[2])
yfit1 <- yfit1*diff(h\$mids[1:2])*length(LC)
yfit2 <- yfit2*diff(h\$mids[1:2])*length(LC)
\# Plot pretty graph
$\mathrm{v} 1=\operatorname{seq}(-0.65,1.35$,length=11) \# offset from minimum bin by 0.05 so that ticks are in middle of bins
$\mathrm{v} 2=\mathrm{c}(0.2,0.32,0.50,0.80,1.26,2.0,3.2,5.0,7.9,12.6,20.0) \#$ actual $\mathrm{ng} / \mathrm{mL}$ values on $\log$ scale
hist(LC, breaks = 20, density = 10, col = "purple", xaxt="n", xlab = "Plasma [11-kt] (ng/mL)", ylim = c(0, 140), main = "Plasma [11-kT] in Yakima River Juvenile Males")
lines(xfit, yfit1, col="red", lwd=2)
lines(xfit, yfit2, col="blue", lwd=2)
axis(side $=1$, at $=v 1$, labels $=v 2$ )
abline( $\mathrm{v}=$ cutoff, col="green", lty=2, lwd=2)
text(0.05,135, paste("Minijack cutoff", " $\mathrm{n}=$ =", round(10^(cutoff), 2),"(ng/mL)"))

[^0]:    ${ }^{1}$ Adapted from the Hatchery Reform Project, the Hatchery Science Review Group reports and independent science review.

[^1]:    ${ }^{2}$ website: http://www.psmfc.org/Regional Mark Processing_Center_RMPC

[^2]:    ${ }^{3}$ There could have been some hatchery-origin fish with an intact adipose fin. Although all summer/fall Chinook hatchery programs in the Upper Columbia strive for a $100 \%$ adipose fin clip rate, a small percentage ( $\sim 1 \%$ ) may not receive the fin clip due to mechanical failure in the marking trailer. Additionally, not all fall Chinook programs, such as Priest Rapids Hatchery, clip the adipose fin of their releases.

[^3]:    ${ }^{4}$ This $80 \%$ correction factor has also been suggested by the HSRG as a default value when no direct estimates are available (HSRG 2009). Also see HSRG 2014 for a discussion about the definition and calculation effective pHOS.

[^4]:    ${ }^{5}$ A radio tracking study showed that fewer than $50 \%$ of the natural-origin fish tagged at Wells Dam ended up in the Okanogan in 2011 and 2012 (Mann and Snow 2013).

[^5]:    ${ }^{6}$ Not all hatchery steelhead released in the Okanogan receive an adipose fin clip. In 2019, 183,353 steelhead were released into the Okanogan River with an adipose clip, and 18,197 unclipped steelhead were released.

[^6]:    ${ }^{7}$ Origin assignments take into account all scale, ad-mark, coded wire tag and PIT tag information available at time of publication. Values may be updated in future annual reports depending on availability of data.

[^7]:    ${ }^{1}$ Number of days to $90 \%$ passage was based on the mid-point of the release dates, which can vary by several weeks year to year

[^8]:    ${ }^{8}$ From McElhany, 2000 (NOAA), a viable salmonid population is an independent population of any Pacific salmonid (genus Oncorhynchus) that has a negligible risk of extinction due to threats from demographic variation, local environmental variation, and genetic diversity changes over a 100-year time frame. The four VSP parameters are abundance, productivity, spatial structure, and diversity.

[^9]:    ${ }^{(1)}$ Includes mini jacks
    ${ }^{(2)} 24 \%$ AD Present steelhead were HORs
    ${ }^{(3)} 67 \%$ AD Present steelhead were HORs
    ${ }^{(4)} 147$ adults ( 80 males, 67 females) taken for transfer to Eastbank Hatchery
    ${ }^{(5)} 98$ males and 98 females taken in July and August,
    ${ }^{(6)}$ Surplussed fish
    RTS $=$ Return to stream
